SIR,—Since publication of my article (Feb 3), my attention has been drawn to the earlier papers of Barber on the administration of sulphonamides for chronic lupus erythematosus He was treating patients as early as 1938[1] and made a report in 1940[2] summarising his experiences It is quite evident that he was well aware of the hazards of this form of treatment He stated

> Apart from the serious and sometimes fatal effects that may follow the administration of sulphonamides even in moderate dosage the severity of the reactions that often result from their use in lupus erythematosus makes it imperative that they should be given with the greatest discretion It cannot be too strongly emphasised that the indiscriminate use of the sulphonamides is fraught with danger

Further confirmation of the responsibility of the sulphonamides has come from the U S A Wile[3] has stated

> The incidence of this group has increased amazingly during the past fifteen or twenty years I believe this increase is real rather than apparent At the University Hospital (Ann Arbor Mich.) there has been an increase of 450% over this period Coincident in time with this increase there came in to the picture the more or less general use of the sulphonamide drugs, first used for serious infections such as pneumonia It soon became a general habit for many people to use sulphonamides for common colds and for all types of infections Many of these patients are photo sensitive and these drugs have shown themselves to be photo sensitizing agents

I have also had many letters from other observers supporting this thesis

London W 1 STEPHEN GOLD

INTRAVENOUS IRON

SIR,—Dr Klopper, commenting (March 3) on the recent work of Dr Scott and Dr Govan (Feb 17) shares with them a difficulty in interpreting the percentage utilisation of iron administered intravenously during pregnancy I would like to draw attention to a mathematical observation which occurred to me when I was engaged in similar work three years ago

In the absence of iron deficiency as pregnancy advances there is a slight increase in the total amount of circulating hæmoglobin but for the purpose of this note let it be assumed that it remains constant In a perfectly normal pregnancy, where no iron deficiency can be shown to exist at about the 30th week of gestation quite a usual finding would be a hæmoglobin level of 75% Now this fall in percentage is due to fluid retention and consequent hæmodilution and a finding of 75% Hb is produced by the same total circulating hæmoglobin that gave a reading of 100% before pregnancy began Treatment of such a case on the non pregnant basis that 100 mg elemental iron will result in a 4% increase in the hæmoglobin level, will obviously result in a finding that the utilisation of iron is nil.

Further, assume a similar case, but one with demonstrable iron deficiency anæmia and in which the hæmoglobin level is 70% If the hæmodilution is the same in this case, this hæmoglobin level represents a non-pregnant level of $\frac{100}{75} \times 70 = 93\%$ Such a case is therefore not 30% deficient in hæmoglobin, but 7%, and the anæmia should be corrected by the injection of 200 mg iron, and not 750 mg as would appear at first sight If 750 mg iron were injected, it is evident that some large quantity, in the region of 500 mg, would be diverted to storage depots and the calculated percentage utilisation would be very low

It will be seen therefore, that the treatment by present methods of iron deficiency anæmia in pregnancy results in gross overdosage In practice this is a good thing, for the reason that the very presence of an iron-deficiency anæmia in pregnancy is an indication that depot stores of iron are very low and that they would benefit from the excess dosage

The problem of iron deficiency anæmia in pregnancy is obscured by a lack of clear understanding of the total circulating blood-volume during pregnancy

PERSONAL HYGIENE

SIR,—Dr Bourne (Jan 27), stressing the importance of cleansing the hands from any fæcal contamination, suggests the fitting of foot controls for flushing the cistern, opening the door of the W C, and turning the tap over the basin A far more practicable suggestion is that all elementary school teachers should instruct their children that what might be called the toilet paper hand should never be used for these operations until cleaned It is extraordinary how quickly this habit can be learned so that it is repulsive to the child for that hand to be used for these purposes until it has gone under the tap

Petworth Sussex A H SPICER

CORTISONE AND FAT METABOLISM

SIR,—It is generally assumed that adrenocorticotropic hormone and other anterior pituitary hormones influence fat mobilisation and increase the fat content of the liver, but the influence of 'Cortisone' on fat metabolism has not yet been ascertained In clinical research Sprague et al,[1] Adlersberg et al.,[2] and Sala et al.[3] have found that cortisone increases plasma phospholipids and cholesterol. According to Winter et al,[4] Kobernick and More,[5] and Rich et al.,[6] it produces hyperlipæmia in rats and rabbits Payne,[7] on the other hand, minimises the rôle of adrenal cortex in fat metabolism, and Levin and Farber[8] deny that cortisone may provoke fatty liver

We have determined the fat content of the liver in two groups of adult male rats, respectively treated daily with 1 and 5 mg of cortisone for 70 and 20 days.

The rats were fed a diet consisting of 56% carbohydrate 30% protein 10% fat with adequate supplement of salts vitamins and lipotropic factors The experimental groups consumed the same quantity of food daily Dried and powdered liver was extracted with ether by reflux distillation The fat content of the livers was significantly higher in cortisone treated animals than in controls (P values of 0·99 determined by the use of Student's *t*) Post-mortem examination showed varying degrees of hepatic perilobular steatosis without necrotic foci or fibrous proliferation body fat was

LYSIVANE AND ARTANE IN PARKINSONISM

SIR,—Dr Garai's conclusions (Feb 24) are most interesting My experience has been that 'Artane' is much more effective in postencephalitic parkinsonism than in the idiopathic and arteriosclerotic varieties, and Dr Garai's findings support this Of 31 postencephalitic patients 7 (23%) showed no improvement, whereas of 18 patients suffering from idiopathic and arteriosclerotic parkinsonism 6 (33%) were not improved

The large doses used by Dr Garai invite comment I find that where artane is effective, improvement is apparent on the second or third day [1] Where this does not occur, persistence with the drug is unlikely to result in success Canelis et al [2] noted improvement within three days, continuing up to the end of the second week Dr Garai writes "it was found necessary in most cases to exceed 50 mg before full benefit was obtained" Was this the optimum dose, and was the benefit so obtained any the less when this was reduced to 20 mg or less daily ?

I agree that amphetamine has a potentiating effect on artane, especially in the control of oculogyric crises Where the number and severity of these is not satisfactorily reduced by artane alone, the addition of amphetamine may bring about the desired effect

Liverpool B K ELLENBOGEN

CAFESTOL IN RHEUMATOID ARTHRITIS

SIR,—In their letter of a year ago, Ferrari and Allegri [3] reported good results with 'Cafestol,' a new preparation obtained from the unsaponifiable fraction of the seed of *Coffea arabica* L, in 16 patients with polyarthritis due to rheumatic fever, rheumatoid arthritis, ankylosing spondylitis, or degenerative arthritis of the spine The beneficial effects were more evident in the acute inflammatory disorders than in the degenerative Pain was rapidly diminished and there was progressive reduction in the articular swelling, temperature, and erythrocyte sedimentation rate (E S R) A steroid configuration has been ascribed to this vegetable substance, which Ferrari and Allegri claim to have the same clinical applications as the most potent steroids of animal origin, such as 'Cortisone' Their letter gave only a brief preliminary report without any clinical or experimental details

Cafestol is manufactured in Italy and marketed by Messrs Simes, of Milan So far we have not obtained any literature on the pharmacological or clinical aspects of this substance However, we received 3000 mg of the original substance, as marketed in Italy, for clinical trial, in addition to 3000 mg of a British substitute prepared especially for research investigations The Italian preparation was dissolved in olive oil, whereas the British substitute was dissolved in propylene glycol, and both were packed in ampoules containing 100 mg In view of these very limited supplies the investigation has been made on two patients only, each preparation being used entirely on one patient

Italian Cafestol

A married woman aged 45 had had rheumatoid arthritis for 22 years The onset was afebrile, insidious, and polyarticular There was no family history of rheumatism Five days before this trial began, the patient was admitted to hospital as an urgent case because of a sudden relapse, both hands, knees, and ankles being painful, swollen and tender Radiography of her hands showed that she had stage 3 rheumatoid arthritis, according to the Steinbrocker classification [4] After clinical and laboratory investigations she was given 400 mg of cafestol intramuscularly daily for three days and then 200 mg daily for nine days, making a total of 3000 mg After this her joint pains were slightly less, movements of the affected joints were a little easier, and the range of movements was slightly greater The pain in the knees, which was severe at the beginning of the course, became much less by the end of the course, and there were no new sites of pain. The laboratory findings (see table) show no significant changes in the E S R , packed cell volume, plasma viscosity, or serum levels of sodium, potassium, or chlorides

In both cases daily intramuscular injections were begun on Dec. 6
* Spa hospitals method corrected rate

On the fifth day of the injections the patient complained of intermittent nausea which had begun soon after she started the injections and had got worse each day She did not vomit at any time She also complained of a "persistent taste of chlorodyne," which became less intense on the fifth day Visiting relations and fellow patients all said they could smell chlorodyne in her breath, but we could not detect the smell So far as could be ascertained, she had not eaten or drunk anything containing chlorodyne or similar substances, and so far as we know, none is present in cafestol This symptom became less pronounced on the day after the daily dose of cafestol was reduced from 400 to 200 mg Nothing abnormal was detected in the urine, and no explanation can be offered for the curious statements

At the end of the course the patient appeared to be happy, full of optimism and generally improved, in spite of the negative laboratory findings

British Substitute

A young unmarried woman, aged 22, had had rheumatoid arthritis in the interphalangeal joints of both hands for 2 years The onset was afebrile, insidious, and polyarticular, the hips, ankles, elbows, and shoulders being affected in turn She had been in hospital for six weeks when the present trial was begun All her interphalangeal joints and both wrists were swollen and painful, with much restriction of movements Radiography showed a stage 2 rheumatoid arthritis. The left acromioclavicular joint was also involved She walked with pain and some difficulty There was no family history of rheumatism The eosinophil count (80 per c mm) showed no response to adrenaline

She was given 400 mg of the British substitute for cafestol intramuscularly daily for three days, followed by 200 mg daily for nine days, making a total of 3000 mg During the course there was a gradual reduction in her joint pains and she became much more cheerful

At the end of the course she had improved slightly, more particularly as regards pain, but it would be hard to say whether the improvement was greater than might have been expected from her condition before the course The laboratory findings (see table) showed no significant changes

Both these patients showed some clinical improvement, mainly in a diminution of their pain The improvement was slightly greater in the patient given the Italian cafestol, but the results were much less definite than one might have expected from the letter of Ferrari and Allegri [3]

SULPHONAMIDES AND PENICILLIN IN THE PATHOGENESIS OF SYSTEMIC LUPUS ERYTHEMATOSUS

SIR —Since publication of my article (Feb 3), my attention has been drawn to the earlier papers of Barber on the administration of sulphonamides for chronic lupus erythematosus He was treating patients as early as 1938[1] and made a report in 1940[2] summarising his experiences It is quite evident that he was well aware of the hazards of this form of treatment He stated

> ' Apart from the serious and sometimes fatal effects that may follow the administration of sulphonamides even in moderate dosage the severity of the reactions that often result from their use in lupus erythematosus makes it imperative that they should be given with the greatest discretion It cannot be too strongly emphasised that the indiscriminate use of the sulphonamides is fraught with danger '

Further confirmation of the responsibility of the sulphonamides has come from the U S A Wile[3] has stated

> ' The incidence of this group has increased amazingly during the past fifteen or twenty years I believe this increase is real rather than apparent At the University Hospital (Ann Arbor Mich.) there has been an increase of 450% over this period Coincident in time with this increase there came in to the picture the more or less general use of the sulphonamide drugs first used for serious infections such as pneumonia It soon became a general habit for many people to use sulphonamides for common colds and for all types of infections Many of these patients are photo sensitive and these drugs have shown themselves to be photo sensitizing agents "

I have also had many letters from other observers supporting this thesis

London W 1 STEPHEN GOLD

INTRAVENOUS IRON

SIR,—Dr Klopper, commenting (March 3) on the recent work of Dr Scott and Dr Govan (Feb 17), shares with them a difficulty in interpreting the percentage utilisation of iron administered intravenously during pregnancy I would like to draw attention to a mathematical observation which occurred to me when I was engaged in similar work three years ago

In the absence of iron deficiency, as pregnancy advances there is a slight increase in the total amount of circulating hæmoglobin, but for the purpose of this note let it be assumed that it remains constant In a perfectly normal pregnancy, where no iron deficiency can be shown to exist, at about the 30th week of gestation quite a usual finding would be a hæmoglobin level of 75% Now this fall in percentage is due to fluid retention and consequent hæmodilution and a finding of 75% Hb is produced by the same total circulating hæmoglobin that gave a reading of 100% before pregnancy began Treatment of such a case on the non pregnant basis that 100 mg elemental iron will result in a 4% increase in the hæmoglobin level, will obviously result in a finding that the utilisation of iron is nil.

Further, assume a similar case, but one with demonstrable iron deficiency anæmia, and in which the hæmoglobin level is 70% If the hæmodilution is the same in this case, this hæmoglobin level represents a non-pregnant level of $\frac{100}{75} \times 70 = 93\%$ Such a case is therefore not 30% deficient in hæmoglobin, but 7%, and the anæmia should be corrected by the injection of 200 mg iron, and not 750 mg as would appear at first sight If 750 mg iron were injected, it is evident that some large quantity, in the region of 500 mg, would be diverted to storage depots and the calculated percentage utilisation would be very low

It will be seen therefore, that the treatment by present methods of iron deficiency anæmia in pregnancy results in gross overdosage In practice this is a good thing, for the reason that the very presence of an iron-deficiency anæmia in pregnancy is an indication that depot stores of iron are very low and that they would benefit from the excess dosage

The problem of iron deficiency anæmia in pregnancy is obscured by a lack of clear understanding of the total circulating blood-volume during pregnancy

PERSONAL HYGIENE

SIR,—Dr Bourne (Jan 27), stressing the importance of cleansing the hands from any fæcal contamination, suggests the fitting of foot controls for flushing the cistern, opening the door of the W C , and turning the tap over the basin A far more practicable suggestion is that all elementary school teachers should instruct their children that what might be called the toilet paper hand should never be used for these operations until cleaned It is extraordinary how quickly this habit can be learned so that it is repulsive to the child for that hand to be used for these purposes until it has gone under the tap

Petworth Sussex A H SPICER

CORTISONE AND FAT METABOLISM

SIR,—It is generally assumed that adrenocorticotropic hormone and other anterior pituitary hormones influence fat mobilisation and increase the fat content of the liver , but the influence of ' Cortisone ' on fat metabolism has not yet been ascertained In clinical research Sprague et al ,[1] Adlersberg et al ,[2] and Sala et al[3] have found that cortisone increases plasma phospholipids and cholesterol. According to Winter et al ,[4] Kobernick and More,[5] and Rich et al ,[6] it produces hyperlipæmia in rats and rabbits Payne,[7] on the other hand, minimises the rôle of adrenal cortex in fat metabolism, and Levin and Farber[8] deny that cortisone may provoke fatty liver

We have determined the fat content of the liver in two groups of adult male rats, respectively treated daily with 1 and 5 mg of cortisone for 70 and 20 days

The rats were fed a diet consisting of 56% carbohydrate, 30% protein 10% fat with adequate supplement of salts vitamins and lipotropic factors The experimental groups consumed the same quantity of food daily Dried and powdered liver was extracted with ether by reflux distillation The fat content of the livers was significantly higher in cortisone treated animals than in controls (P values of 0·99 determined by the use of Student s *t*) Post-mortem examination showed varying degrees of hepatic perilobular steatosis without necrotic foci or fibrous proliferation body fat was

LYSIVANE AND ARTANE IN PARKINSONISM

SIR,—Dr Garai's conclusions (Feb 24) are most interesting My experience has been that 'Artane' *is much more effective in postencephalitic parkinsonism* than in the idiopathic and arteriosclerotic varieties, and Dr Garai's findings support this Of 31 postencephalitic patients 7 (23%) showed no improvement, whereas of 18 patients suffering from idiopathic and arteriosclerotic parkinsonism 6 (33%) were not improved

The large doses used by Dr Garai invite comment I find that where artane is effective, improvement is apparent on the second or third day [1] Where this does not occur, persistence with the drug is unlikely to result in success. Canelis et al [2] noted improvement within three days, continuing up to the end of the second week Dr Garai writes "it was found necessary in most cases to exceed 50 mg before full benefit was obtained" Was this the optimum dose, and was the benefit so obtained any the less when this was reduced to 20 mg or less daily ?

I agree that amphetamine has a potentiating effect on artane, especially in the control of oculogyric crises Where the number and severity of these is not satisfactorily reduced by artane alone, the addition of amphetamine may bring about the desired effect

CAFESTOL IN RHEUMATOID ARTHRITIS

SIR,—In their letter of a year ago, Ferrari and Allegri [3] reported good results with 'Cafestol,' a new preparation obtained from the unsaponifiable fraction of the seed of *Coffea arabica* L , in 16 patients with polyarthritis due to rheumatic fever, rheumatoid arthritis, ankylosing spondylitis, or degenerative arthritis of the spine The beneficial effects were more evident in the acute inflammatory disorders than in the degenerative Pain was rapidly diminished and there was progressive reduction in the articular swelling, temperature, and erythrocyte sedimentation rate (E S R) A steroid configuration has been ascribed to this vegetable substance, which Ferrari and Allegri claim to have the same clinical applications as the most potent steroids of animal origin, such as 'Cortisone' Their letter gave only a brief preliminary report without any clinical or experimental details

Cafestol is manufactured in Italy and marketed by Messrs Simes, of Milan So far we have not obtained any literature on the pharmacological or clinical aspects of this substance However, we received 3000 mg of the original substance, as marketed in Italy, for clinical trial, in addition to 3000 mg of a British substitute prepared especially for research investigations The Italian preparation was dissolved in olive oil, whereas the British substitute was dissolved in propylene glycol, and both were packed in ampoules containing 100 mg *In view of these very limited supplies the investigation* has been made on two patients only, each preparation being used entirely on one patient

Italian Cafestol

A married woman aged 45 had had rheumatoid arthritis for 22 years The onset was afebrile, insidious, and polyarticular There was no family history of rheumatism Five days before this trial began, the patient was admitted to hospital as an urgent case because of a sudden relapse, both hands, knees, and ankles being painful, swollen, and tender Radiography of her hands showed that she had stage 3 rheumatoid arthritis, according to the Steinbrocker classification [4] After clinical and laboratory investigations she was given 400 mg of cafestol intramuscularly daily for three days, and then 200 mg daily for nine days, making a total of 3000 mg After this her joint pains were slightly less, movements of the affected joints were a little easier, and the range of movements was slightly greater The pain in the knees, which was severe at the beginning of the course, became much less by the end of the course, and there were no new sites of pain. The laboratory findings (see table) show no significant changes in the E S R , packed cell volume, plasma viscosity, or serum levels of sodium, potassium, or chlorides

LABORATORY FINDINGS

Date 1950	Blood: E S R *	Blood: P C V (%)	Blood: Plasma viscosity	Blood: Eosinophils per c mm	Serum levels (mg per 100 ml): Sodium	Serum levels (mg per 100 ml): Potassium	Serum levels (mg per 100 ml): Chlorides	Urinary ketosteroids (mg per 24 hr)

In both cases daily intramuscular injections were begun on Dec. 6
* Spa hospitals method corrected rate

On the fifth day of the injections the patient complained of intermittent nausea which had begun soon after she started the injections and had got worse each day She did not vomit at any time She also complained of a "persistent taste of chlorodyne," which became less intense on the fifth day Visiting relations and fellow patients all said they could smell chlorodyne in her breath, but we could not detect the smell. So far as could be ascertained, she had not eaten or drunk anything containing chlorodyne or similar substances, and so far as we know, none is present in cafestol This symptom became less pronounced on the day after the daily dose of cafestol was reduced from 400 to 200 mg Nothing abnormal was detected in the urine, and no explanation can be offered for the curious statements

At the end of the course the patient appeared to be happy, full of optimism and generally improved, in spite of the negative laboratory findings

British Substitute

A young unmarried woman, aged 22, had had rheumatoid arthritis in the interphalangeal joints of both hands for 2 years The onset was afebrile, insidious, and polyarticular, the hips, ankles, elbows, and shoulders being affected in turn She had been in hospital for six weeks when the present trial was begun All her interphalangeal joints and both wrists were swollen and painful, with much restriction of movements Radiography showed a stage 2 rheumatoid arthritis The left acromioclavicular joint was also involved She walked with pain and some difficulty There was no family history of rheumatism The eosinophil count (80 per c mm.) showed no response to adrenaline

She was given 400 mg of the British substitute for cafestol intramuscularly daily for three days, followed by 200 mg daily for nine days, making a total of 3000 mg During the course there was a gradual reduction in her joint pains and she became much more cheerful

At the end of the course she had improved slightly, more particularly as regards pain, but it would be hard to say whether the improvement was greater than might have been expected from her condition before the course The laboratory findings (see table) showed no significant changes

Both these patients showed some clinical improvement, mainly in a diminution of their pain The improvement was slightly greater in the patient given the Italian cafestol, but the results were much less definite than one might have expected from the letter of Ferrari and Allegri [3] will be far greater in number than ever before. In the outer zone of a bombed area there may be thousands of injured and the majority will have limb injuries. Admittedly radiation effects may complicate management, and at the moment this problem occupies much attention. At the same time it seems essential to plan for a more adequate instruction of surgeons who can handle these casualties. Just as with burns, some standard method of treatment is necessary, so some direction is urgently required for the care of large numbers of limb injuries.

There is a danger of complacency here with the suggestion that anyone can sew up a few flesh wounds or set fractures. This is the careless attitude which produced the disasters of primary suture, inadequate wound excision or decompression, and faulty splintage—disasters repeated so often in the last war. Such errors are avoidable and there should be no excuse for their repetition.

University of Liverpool

JOHN A. SHEPHERD

Obituary

PERCY STANLEY TOMLINSON

K.B.E., C.B., D.S.O., F.R.C.P., F.R.C.P.E.

MANY who served in the Royal Army Medical Corps during the late war will have learnt with deep regret of the death on March 6 of Major-General Sir Percy Tomlinson.

Born in 1884, he was the son of Colonel W. W. Tomlinson, R.A.M.C., and was educated at Clifton College and Bristol University. He entered the Corps in 1909, and during the first world war served in France and Macedonia, gaining three mentions in despatches and the D.S.O. After service at home and in India, he found himself at the outbreak of the second world war D.D.M.S. to British troops in Egypt. In April, 1940, he was appointed D.M.S. to the Middle East Force, and he held that post during the critical years of the fighting in Africa. In 1943 he handed over this post to Major-General W. C. Hartgill, and in 1944 he was appointed D.M.S. in North-west Europe.

[Stoneman

He will be remembered above all for his magnificent work in Egypt, where he faced problems of the greatest difficulty, many of them new to military medicine. He was in charge of a large composite force, whose medical units came from every part of the British Empire and its Allies. He was dealing with a territory that stretched two thousand miles from north to south and two thousand miles from east to west, in which every terrain and every climate might be encountered, in which epidemic diseases were as much a danger to the armies as the warfare of the enemy, and in which hygiene and preventive medicine were of supreme importance. He directed the medical service of a force that till the last phases was outnumbered and under-equipped, that had to face misfortune and retreat as well as victory. He held office during the lightning changes of the early desert campaigns, and during the fighting in Greece and Crete, in Syria, Iraq, and Eritrea. He had to plan for possible disaster when Rommel stood within a day's march of the Cairo-Alexandria road, and had to improvise an emergency medical base on the Red Sea near the Abyssinian border in preparation for a possible loss of the Suez Canal, within a few months he was organising the medical preparations for the battle of Alamein, and coping with the difficulties of the chase of Rommel from Alexandria to Tunis—the longest and fastest advance in military history, with the sole exception of Cunningham's dash from Kenya to Addis Ababa.

In all this work he was not merely accessible to his subordinates, he sought out experts in every branch of medicine, posed his problems, and used their advice. He had a sound knowledge of clinical medicine, a fine administrative brain, and the power of leadership to an unusual degree. He could think clearly and decide quickly and impartially.

The changes that occurred under his leadership were fundamental. Forward surgery was reorganised to meet the needs of mechanised warfare. The field surgical units were planned and improved. The blood-transfusion service was organised and developed till blood became the chief factor in the remarkable rise in recovery from abdominal injuries and fall in the incidence of gas gangrene that marked the desert campaigns, and the field transfusion officer became the key man of the advanced operating centres. Advanced parties of the neurosurgical, faciomaxillary, and ophthalmic units were for the first time grouped at casualty-clearing stations within a few hours of the front line. At the same time our armies were kept almost free from the infective diseases, particularly the dysenteries, that seriously hampered our enemies.

In the second world war Tomlinson was mentioned four times in despatches. In 1941 he was made an honorary physician to the King and was appointed C.B., in 1943 he received a knighthood in the Order of the British Empire, and he held the Croix de Guerre, the Legion of Honour, and the Legion of Merit of the U.S.A. He was elected a fellow of the Royal College of Physicians in 1943, and an honorary fellow of the Royal College of Physicians of Edinburgh in 1946.

General Tomlinson married Miss Gertrude Barr in 1920. He had one son, who was killed on active service, and one daughter.

GEORGE MILTON SMITH

M.D. Columbia, LL.D. Yale

As director of the Anna Fuller Fund Dr. G. M. Smith was able to foster Anglo-American coöperation in medical research, and many scientific workers will remember the warm kindliness which he added to official grants.

George Milton Smith graduated A.B. at Yale in 1901 and M.D. at Columbia University three years later. In 1910 he became associate professor of pathology in Washington University, St. Louis, where he worked till 1934. He then returned to Yale to take up his appointment with the Anna Fuller Fund, which he still held at the time of his death. While in Yale he also acted as research associate in anatomy. In later years his research interests lay mainly in the comparative pathology of tumours, on which he published papers in *Zoologica* and elsewhere, and in historical medicine. His greatest achievement, however, rests in the advancement of medical research, not only in the United States but in other countries, through his work for the Anna Fuller Fund and as adviser to the Jane Coffin Childs Memorial Fund for Medical Research. Much of his contribution lay in cancer research, and he also acted as a member of the National Advisory Cancer Council from 1939 to 1942. Yale conferred on him the honorary degree of LL.D. in 1947. A devoted supporter of the Allied cause in the late war, he served as chairman of the National Research Council committee on armoured vehicles.

A British colleague writes: "In George Smith we admired his intense loyalty to his country and to Yale, his complete unselfishness, and his lasting belief in international coöperation in science and medicine. He was also able, and wont, to accompany his practical benefactions with the warmth of encouragement to a rare degree. His loss will be mourned, and his memory honoured, by a host of colleagues and friends the world over."

decreased considerably, interscapular brown fat was reduced in amount and had taken the appearance of white adipose tissue

From our results it appears that cortisone increases the fat content of liver, probably through an increase of fat mobilisation Fatty liver produced by ACTH may be regarded as a consequence of adrenal stimulation

METHONIUM COMPOUNDS IN HYPERTENSION

SIR,—In their letter last week, Dr Hirson and Dr Kelsall describe a fatality due to excessive low blood pressure after administration of hexamethonium An attempt was made to raise the blood-pressure by an intravenous drip containing adrenaline, and the report notes that the "pressure always dropped precipitately during the brief periods when the drip was discontinued"

It does not appear to be generally known that this result is to be expected, since it has been shown that *adrenaline itself has a blocking action on sympathetic* ganglia If an intravenous infusion of adrenaline is given, the adrenaline by direct action on the vessel walls causes vasoconstriction, but, by its action on sympathetic ganglia, it prevents the stream of impulses emitted by the vasomotor centres from reaching the vessels When the adrenaline infusion is stopped, the direct action on the vessels disappears, and, because tonic impulses from the centre cannot pass the ganglia, the blood-pressure falls precipitately In this respect noradrenaline has the same action as adrenaline

Fortunately, however, posterior lobe extract of the pituitary gland has no such effect, and, so far as animal experiments afford a guide, the right treatment of a patient in whom the blood pressure has fallen low because of the action of hexamethonium would seem to be to give an intravenous drip containing 10 units pituitary (posterior lobe) extract in each 50 ml. saline We have some evidence, which is too little to be conclusive, that posterior lobe extract may increase ganglionic transmission, and therefore it may prove to be a positive antidote to ganglionic block However this may be, the interruption of a drip containing posterior lobe extract would certainly not be followed by the precipitate fall of blood pressure which occurs at the end of an adrenaline drip

In using an intravenous drip containing posterior lobe extract, the effect on the coronary vessels will be constrictor, and therefore the drip should be given slowly

The evidence for the action of adrenaline on ganglionic transmission will be found in the *Journal of Physiology* (1942, **101**, 289)

J H BURN

ANTITOXINS AND ANTIBIOTICS

SIR,—Some of the most potent poisons known at the present time are bacterial toxins, so called "bacteriological warfare" is based on knowledge of these substances

Antibiotics deal faithfully with bacteria but offer no protection against their products Antitoxic treatment is a routine for cases of diphtheria, tetanus, and botulism, and with less effect for gas gangrene due to *Clostridium welchii* with its multiplicity of toxins, occupying half the letters of the Greek alphabet It is not generally realised that *Streptococcus pyogenes* can produce a powerful multi type toxin, and also the common *Staphylococcus pyogenes*, in certain instances, can produce an "enterotoxin" and, more often, cell destroying and blood clotting toxins Before antibiotics came into use, streptococcal antiserum and staphylococcal antitoxin were often used, with uneven results

The brilliant effects of treatment with antibiotics seem to have discouraged the serologists who formerly worked enthusiastically on the improvement of antisera. One or two recent tragedies have underlined our lack of effective sera, and also the fact that the present generation seems to have forgotten that such things exist or can be used with success

One such case was a young woman with a (staphylococcal) infected wisdom root This was operated on, and the woman died two days later of a pulmonary embolism despite active antibiotic therapy I think she might have been saved by simultaneous antibiotic and staphylococcal antitoxin treatment *Another young woman developed localised osteomyelitis* in a metatarsal bone, and died of general peripheral circulatory failure, despite the exhibition of astronomical doses of antibiotics

I think that a streptococcal toxin was to blame for the unfortunate outcome in the second case, but it never occurred to anybody to try antistreptococcal serum Nobody was really to blame for the fatal termination in either case, but I would like to suggest that the serologists be encouraged to get busy again, and develop their art to the utmost, and perhaps advertise their products

Epping, Essex

FRANK MARSH

WILL WE NEVER LEARN ?

SIR,—After an interval of five weeks the first comment appears on a report by Surgeon Commander Latta (*Lancet*, Jan 27) on casualties in the Korean campaign He stressed two important points (1) that primary suture of war wounds is usually disastrous, (2) that rapid evacuation of casualties from a war zone can be a mixed blessing That he has to stress these points bears out Sir Heneage Ogilvie's text "Will we never learn ?" I think Commander Latta has done a considerable service in making his clear and unbiased report

As Sir Heneage indicates (March 3), there is something wrong with the training of the military surgeon As a reservist in one Service before the late war I used to do periods of training In my youthful enthusiasm I expected to be taught something about war surgery But no one seemed very interested, and the Service journals in periods of peace bear witness to this extraordinary lack of attention to a subject which should be very much in the minds of Service doctors—particularly surgical specialists The non-medical branches of the Services in peace time prepare for war, but for some reason the doctors do not There should be intensive training in the surgery of trauma for both regulars and reservists Suitable courses could easily be arranged and interested tutors would not be lacking The individual is not usually prepared to educate himself in these matters, and so he must be subjected to some discipline as Sir Heneage suggests *It would at least be* possible to drum into everyone concerned the principles of treatment of soft tissue wounds No one would expect to train abdominal surgeons, thoracic surgeons, or neurosurgeons in a night, but it ought to be feasible to teach most Service medical officers how to diminish mortality and morbidity in the major group of war wounds

I have long believed that the conscientious perusal of Professor Trueta's small monograph on war surgery published in 1939 would have saved a lot of needless suffering I still think that most of the answers are in this book (For one thing it scarcely mentions chemotherapy or antibiotic therapy—an unwarranted faith in these has often lead to the neglect of surgical principles) Jolly's *Field Surgery in Total War* was another book of great value in those early years The point is that remarkably few bothered to read these books in 1939 and 1940, and it does look as if appropriate study must be directed

If there is another war and if, as is *all too likely*, there is intensive bombing—atomic or otherwise—casualties

Congress at Evian

An international medical congress will be held at Evian from Sept. 7 to 9 under the presidency of Prof. E. Chabrol. The topic chosen for discussion is L'eau en biologie et en clinique. Further particulars may be had from Prof. Jean Hamburger, 29, Boulevard de Courcelles, Paris.

Gerontological Congress

The second International Gerontological Congress will be held at St. Louis, Missouri, from Sept. 9 to 14 under the presidency of Dr. E. V. Cowdry. Further information may be had from the secretary of the congress, Washington University Medical School, 660, South Kingshighway, St. Louis 10, Mo.

European Congress on Rheumatism

The Sociedad Española de Reumatismo is organising the second European Congress on Rheumatism, which is to take place at Barcelona from Sept. 24 to 27. The English speakers will include Dr. W. S. C. Copeman, Dr. R. M. Mason, and Dr. L. G. C. Pugh. Further particulars may be had from the general secretary, Via Layetana, 31, Barcelona, Spain.

Medical Research Council Publications

The list of Medical Research Council publications is brought up to date at March 31, 1950, by a new Stationery Office pamphlet (Government publications, sectional list no. 12). This catalogue does not include publications in scientific journals, which are listed in the Council's annual reports. Those wishing to be notified when new M.R.C. publications appear should notify the director of publications (P. 2), H.M. Stationery Office, 429, Oxford Street, London, W.1. Those ordering by post may, if they wish, open deposit accounts with the Stationery Office; deposits (minimum £1) should be sent to P.O. box 569, London, S.E.1.

Institute of Biology

A symposium on Freeze-drying will be held in London on June 29 and 30. Provisional arrangements have been made to hold four sessions. At the first there will be discussions on Physical Principles including freezing and drying of proteins and protein-containing materials such as plasma and foodstuffs, and Dr. R. L. N. Greaves will be in the chair. At the second the Drying of Bacteria and Antibiotics will be discussed (chairman Sir Alexander Fleming, F.R.S.), at the third the Drying of Viruses and Vaccines (chairman Dr. C. H. Andrewes, F.R.S.), at the fourth the Drying of Tissues and Tissue Sections (chairman Prof. J. F. Danielli, D.SC.). Attendance will not be limited to members of the institute, and those who are interested are invited to apply to the general secretary of the institute, Tavistock House South, Tavistock Square, W.C.1.

Medical Society of London

At this society's 171st anniversary dinner, on March 8, Lord Woolton spoke genially of medicine past and present. He recalled that just after the society was founded Guy's Hospital—the hospital of the society's president, Dr. A. H. Douthwaite—was well known for the number of bugs and vermin that it harboured. There had been great changes. As to present-day medical practice: "You are such experts on such small parts of the anatomy that I wonder what chance the human being has of being understood as a whole." Speaking of his own experience as war-time Minister of Food, he said that he had deliberately attempted to preserve the health of the country's children, and the public, having grasped this aim, coöperated whole-heartedly. Lord Woolton was proposing The Society, and in reply the President paid tribute to his policy of fair shares for all. Some, he said, had been confused by the expedients of war: one nursing candidate had described rose hips as the first indication of a threatening bedsore. Turning to the National Health Service, the President suggested that this could be a success if the cleavage between specialist and practitioner were ended, and if the practitioner received a just reward. As to the society itself, its special features were friendliness and the habit it had of drawing together those working in different fields. The President went on to speak gratefully of the gift from Colchester Medical Society of an antique wax medallion of John Coakley Lettsom, the Quaker physician and philanthropist, who founded both societies. The Guests were toasted by Mr. H. R. Thompson, and Dr. W. Russell Brain, P.R.C.P., replied.

Pneumoconiosis as a Prescribed Disease

The Industrial Injuries Advisory Council is considering further the method of prescribing pneumoconiosis as an industrial disease under the National Insurance (Industrial Injuries) Act, 1946. Those interested are invited to submit, by May 1, written evidence to the council's secretary, Mr. S. E. Waldron, O.B.E., Ministry of National Insurance, 30, Euston Square, London, N.W.1. An explanatory memorandum may be had on request.

Association of Workers and Schools for Maladjusted Children

The inaugural meeting of this society was held earlier in the year. A second meeting, to which all who are interested are invited, will be held on Monday, March 19, at the London School of Hygiene, Keppel Street, W.C.1, at 5.15 P.M. The purpose of the meeting is to receive the report of the interim committee, draft rules, and appoint the officers of a permanent committee. The main objects of the association are to find means by which all maladjusted children may be treated, educated, and reabled, to provide a professional body whose opinion would have weight with other bodies, and to encourage research and experiment.

Prescribing and Dispensing in Scotland

The Department of Health for Scotland has told executive councils that in future a selection of prescription forms dispensed each month will be scrutinised centrally to detect and deal with extravagant prescribing under the National Health Service in the light of the Cohen Committee's recommendations. Executive councils will be notified, for consideration in the first place by the local medical committee, of prescriptions which seem extravagant either (*a*) because they contain proprietary preparations for which less expensive standard equivalents may be had, which are not of recognised therapeutic value, or which are advertised direct to the public, or (*b*) because they relate to unduly large quantities of drugs or other items such as lint and cotton wool. The General Medical Services Subcommittee is urging local medical committees to consider very seriously apparent instances of extravagance. These committees will communicate with practitioners concerned, where necessary invite them to attend for discussion with the committee, and in the case of serious or repeated extravagance recommend to executive councils the recovery of appropriate sums. Brief reports of action taken will be furnished by local medical committees to executive councils, which are asked to forward reports to the Department. In appropriate instances the Department will publicise this action (omitting particulars identifying the doctor concerned), and executive councils are asked to supplement, as necessary, such publicity.

Scottish pharmacists have now completed their case for abolishing the 8% cut on earnings imposed last September.

Doctors in the U.S.A.

In 1954 the U.S.A. will have 22,000 fewer doctors than it needs. This estimate was made by Dr. Howard Rusk, chairman of the health resources advisory committee of the U.S. National Security Resources Board, at a meeting in Chicago of the Federation of State Medical Boards. According to B.U.P. Dr. Rusk based his estimate on a military strength of 5 million; if the Forces were not increased beyond $3^1/_2$ million the deficit would be some 20,000. Dr. Rusk was supported by Dr. Joseph Hinsey, of Cornell University Medical College, who declared: "The nation needs more physicians today." Dr. Stockton Kimball, dean of the University of Buffalo Medical College, told the meeting that during the past ten years medical schools had increased their intake to an extent equal to the opening of fifteen new medical schools. Today, he said, there were 26,913 students in medical schools—1090 more than last year and almost 5000 more than ten years ago. The need for more doctors was denied by Mr. Frank Dickinson, PH.D., economist and statistician of the American Medical Association. Medical progress had, he claimed, brought about an increase in "output" of at least one third by each doctor. No-one could foresee the duration of the present emergency, and doctors "cannot become war surplus after a war." Dr. Dickinson pointed out that during the late war about 40% of the active U.S. doctors joined the Forces, but under the care of the remaining 60% the 90% of the total population that was still civilian continued to improve in health.

Notes and News

A SCHOOL FOR HANDICAPPED GIRLS

There were few residential schools for physically handicapped children before 1939, but during the war some 500 of them were evacuated to Peckforton Castle, near Cheshire, and this school remained in action for five years Thanks to the successful experience gained there, similar schools have been established since, and one of these, the London County Council's school at Stapleford Place, near Haywards Heath, in Sussex, was opened by the Minister of Education on Feb 24, The house, built as a private residence in 1911, has been converted according to plans prepared by the architect to the council By August, 1950, it was ready to receive 32 girls and members of the staff who until then had been housed in requisitioned quarters near Sherborne Now there are 49 girls in residence, between the ages of 5 and 16

Some of the children are without homes of their own, others come from homes which are not suitable for a disabled child to live in, and most of them need more medical and nursing care than they could reasonably get in their own homes Parents may visit every month, and the children can go home for holidays if they wish The house is on the village green, which places it well in the middle of the community life, and the neighbours are already taking a friendly interest in the children and in the life of the school Stapleford Place has spacious gardens, plenty of trees and lawns, and a lake of its own—always a gratifying piece of property to a child Its rooms are large and airy, and its windows overlook a lovely stretch of country The alterations have been considerable—a new water supply and sewage disposal system, the installation of modern heating, lighting and cooking equipment, proper fire precautions and a generous increase in bath and lavatory accommodation The panelling and the broad oak staircase have been carefully repaired, and all has been done skilfully, and with the comfort of the children well in mind The aim is to give these girls as nearly as possible a normal education and to fit them for as full an adult life as their disabilities will allow The new venture deserves every success

PORPHYRIN METABOLISM AND PORPHYRIA

With regard to Professor Watson's article last week (p 539), further information has been received about some of the references, as follows

A NEW NORWEGIAN JOURNAL

Norway has a new monthly in the *Journal of the Oslo City Hospitals* Printed in English, this somewhat resembles in form and intention the *Proceedings of the Staff Meetings of the Mayo Clinic* The journal, which will be sent without charge to hospitals in Norway and other countries, is published by Christian Plesner, Hospital and Medical Equipment, Oslo

LYMPHATIC PATHWAYS

A film on the *Lymphatic System* made by the medical film unit of Imperial Chemical Industries in conjunction with Dr J M Yoffey, professor of anatomy at Bristol University, has as its main purpose the instruction of medical students Animated diagrams and beautiful colour cinematography of animal injection experiments with indian ink and Evans blue show in striking terms many features of the mammalian lymphatic system of which students can usually only read Lymphatic trunks in the anæsthetised animals are well seen, and one particularly striking sequence illustrates the passage of substances instilled into the nose reaching the cervical lymphatic pathways The approach of the film is that of experimental physiology, and there is nothing therefore of immediate clinical bearing on lymphatic problems in the human body But as a demonstration of the way in which lymphatic systems work it is a vivid and useful presentation There are two small criticisms the first that some of the animated diagrams go on too long, and the second that the skin incision is shown in the making before each experiment—this might be taken as read after the first time or two

The film, which was briefly reviewed in these columns last year when it was shown at the annual meeting of the British Medical Association,[1] runs for 45 minutes and is 16 mm.

University of Cambridge

Dr F G J Hayhoe has been appointed lecturer in medicine for three years

On March 3 the following degrees were conferred
M A—G K Harrison
M D—P F Borrie, D B Cater, A E Flatt.
M B, B Chir—*Graham Harvey Evers, *Helen M Roseveare *I M Simmonds

*By proxy

University of London

At recent examinations for the academic postgraduate diploma in medical radiology (diagnosis) the following were successful

Raghubar Baidya, A T Broadbridge R J Callander, Phyllis A M. Crozier, David Datt Joseph Friedman J J Geere, J B Hearn, Maurice Hurwitz, Philip Jacobs Edward Mercieca, Victor Roseverne, Morris Simon, D G C Whyte Mary I Wray

Royal College of Surgeons of England

At a meeting of the council on March 8, with Sir Cecil Wakeley, the president, in the chair, a past president's badge was presented to Sir Holburt Waring

Mr A Wallis Kendall and Mr E L Farquharson were elected members of the court of examiners

Mr C D Read was elected to the fellowship ad eundem. The Hallett prize was presented to Mr M W Reece (St. Thomas's Hospital) The council decided that the first award of the James Berry prize would be made in 1952 The subject for essays will be the Treatment and Preservation of the Injured Hand

Prof H H Stones was appointed Charles Tomes lecturer for 1951 It was reported that Dr Loyal Davis (Chicago) will deliver a Moynihan lecture on Oct 9

Scottish Conjoint Board

The following candidates, having passed the final examination, were admitted on March 9 to the licentiateship of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow

Patricia F D Anderson John Boyd G McG Campbell, C MacP Christie Gordon Clarke, D M Cunningham, Anthony de Mello J Y N Devine J A Eykelenboom, Hannah Furman, James Goldie, A E D J Hellegers D W Kidd, Ruth Kope June M Litt, J T Lunn, Rankin Martin Joseph Minsky M H Pinsky Thomas Rice, June Rosin W S Thompson

Royal Society Lectures

Prof R A Peters, M.D, F R S, will deliver the Croonian lecture on June 7 on Lethal Synthesis Dr C H. Andrewes, F.R S, will deliver the Leeuwenhoek lecture on Dec 13 He is to speak on the Place of Viruses in Nature

Postgraduate Course at Hampstead

The Royal Free Hospital group is holding a postgraduate course at the Hampstead General and North West London Hospital, The Green, Haverstock Hill, N W 3, on Thursday of each week from April 5 to June 14 Lecture-demonstrations will begin at 3 P M and 4 15 P M Sir Dan Davies will give the inaugural lecture on April 5 Applications for enrolment should be sent to the secretary of the hospital

Encephalitis and Rabbit Myxomatosis in Australia

Last December the Australian Scientific and Industrial Research Organisation released in rural New South Wales a virus causing myxomatosis in rabbits, to test its effectiveness in controlling the rabbit pest B U.P reports that the disease spread rapidly among rabbits in New South Wales, Victoria, South Australia, and Queensland, but then several people in these areas contracted encephalitis More than 30 cases have been reported in Victoria, and 11 are believed to have died of the disease in Victoria and New South Wales. Government scientists, supported by medical advisers, deny any connection between the release of the virus and the cases of encephalitis, pointing out that exhaustive tests showed that only rabbits were susceptible to the virus and that the 1917 encephalitis outbreak in Queensland and New South Wales attacked people in rural areas but not in large cities. Newspapers have, however, expressed continuing uneasiness, and have cited reports that kangaroos and at least one dog have been found dead with a disorder resembling myxomatosis

DIRECTOR OF PNEUMOCONIOSIS RESEARCH UNIT, MEDICAL RESEARCH COUNCIL

H. W. RODGERS
F.R.C.S.
PROFESSOR OF SURGERY IN THE QUEEN'S UNIVERSITY, BELFAST

In the twenty years that have elapsed since Wolf and Schindler introduced their flexible gastroscope, gastroscopy has become established as a useful, if limited, method of investigation. At the same time it has become clear that accidents occur and that flexibility alone is not enough to ensure complete safety.

Perforation of the upper œsophagus has taken the place of perforation of the stomach and perforation of the lower œsophagus as the most common accident, and Goligher (1948), in reporting one case, was able to collect 17 others from the literature. A bare figure, however, is of little value in assessing the risk of gastroscopy, without some indication of the corresponding number of examinations made. Schindler (1940) surveyed 22,351 gastroscopies performed in America by gastroscopists of varying experience. Among these there was 1 fatal case of hypopharyngeal perforation, also 8 cases of gastric perforation, and 1 of jejunal perforation, all of which recovered. Many English gastroscopists have the impression that accidents are commoner than this, so we have made a survey in this country to determine how often they happen and how they can be prevented.

METHOD OF INVESTIGATION

Forty gastroscopists were invited to coöperate by supplying the following information:

(1) The approximate number of gastroscopies performed under their supervision (*a*) with the Wolf-Schindler gastroscope, and (*b*) with the Hermon Taylor gastroscope.

(2) The number of mishaps, including cases in which the patients recovered, with brief clinical details and a note of the type of instrument and tip used, and whether any accidents had been due to the local anæsthetic.

(3) Whether accidents had happened when an assistant was passing the instrument.

(4) Special precautions recommended to prevent accidents.

All the gastroscopists supplied information, but it was not always complete. The number of gastroscopies performed could often be only roughly estimated, particularly as regards the number performed with each instrument. It must also be supposed that minor non-fatal accidents were less likely to have been recorded than fatal ones. The accident-rates, death-rates, and case-fatality rates are therefore not exact. The reported accident-rate is probably too low, and the case-fatality rate too high; but even if the errors are as great as 50% (which is unlikely), the general conclusions will not be invalidated.

So far as is known, no bias was shown in the selection of gastroscopists written to, because all who were known to one or other of us were included. The large number involved makes it likely that their experience is reasonably representative.

RESULTS

Altogether, 49,000 gastroscopies, with 75 accidents and 32 deaths, were reported. In addition, information was provided about 5 other accidents (with 3 deaths), but the corresponding number of gastroscopies was not known. These have been excluded from table I, in which the main complications with their corresponding incidence and death-rates are recorded, but they have been included in subsequent tables.

Perforation of Œsophagus

Table I shows that the main danger has been perforation of the œsophagus. In most cases the presence of a perforation was either proved at operation or necropsy or demonstrated radiologically. In some the diagnosis of an upper œsophageal perforation was clinical—i.e., based on surgical emphysema of the neck, with or without a localised abscess—in others insufficient evidence was provided for the site to be determined, the report merely referring to "mediastinitis." In 7 cases coming to necropsy no tear could be found, though in 4 of them there was bruising or scratching of the œsophageal mucosa. Since these patients had all died of mediastinal infection, they have been included under the heading of perforation, though they might more accurately be described as cases of periœsophageal infection.

TABLE I—INCIDENCE OF COMPLICATIONS ASSOCIATED WITH 49,000 GASTROSCOPIES

Complication	No. of cases	No. of deaths	Death-rate per 10,000 gastroscopies
Perforation of œsophagus	50	21	4.3
Perforation of stomach	9	1	0.2
Hæmorrhage	7	2	0.4
Miscellaneous	4	4	0.8
Reaction to anæsthetic	5	4	0.8
Total	75	32	6.5

In 1 patient the perforation took place nineteen hours after the passage of the gastroscope and was immediately preceded by violent vomiting. The perforation was in the lower œsophagus, and the case clinically resembled a spontaneous perforation; but it is reasonable to assume that the œsophagus had been damaged at the time of the gastroscopy.

The numbers of cases of each type of perforation reported are shown in table II.

Table II confirms that the preponderant site for perforation is in the upper œsophagus or hypopharynx.

In table III the cases of œsophageal perforation have been subdivided to show the incidence of various possible ætiological factors.

TABLE II—PERFORATION OF ŒSOPHAGUS AND SITE OF LESION*

Site	No. of cases	No. of deaths
Upper œsophagus: proved	23	13
Upper œsophagus: clinical	9	1
Lower œsophagus: proved	4	2
Site indefinite	11	0
No recognisable perforation at necropsy		
Upper œsophageal lesion	4	4
Lower œsophageal lesion	1	1
Site indefinite	2	2
Total	54	23

* Including 4 cases with 2 deaths excluded from table I.

---

* In receipt of an expenses grant from the Medical Research Council.

Merchant-shipping Medical Scales

From April 1, penicillin, chloramphenicol, anti venereal disease outfits, and other items will be added to merchant-shipping medical scales 1 and 2

Malayan Artificial Limbs for South-east Asia

Malaya now makes its own artificial limbs and orthopædic appliances, and also supplies other countries in South east Asia A grant of £7500 from the government of the Federation resulted in the building of a modern factory where 25 craftsmen are employed

How to Look After the Old

A 3–4 months' course, for men and women who wish to become wardens or matrons of homes for old people, will be held in London in October Where necessary some grants are available towards the cost of training Further particulars may be had from the secretary, National Old People's Welfare Committee, 26, Bedford Square, W C 1

Society for the Study of Fertility

The annual conference of this society is to be held at Cambridge on June 20 and 21 The hon. secretaries are Dr G I. M Swyer, University College Hospital, London, W C 1, and Mr A Walton, PH D, A.R C unit of animal reproduction, Animal Research Station, Cambridge The first issue of the society's *Proceedings*, dealing with the Edinburgh conference in 1949, has been published by Messrs W Heffer & Sons Ltd, Cambridge, at 10*s*

Belgian Society of Gastro-Enterology

This society are once more asking their colleagues from other countries to take part in their annual meeting, which they are holding this year at 9 A M on Sunday, June 3, at the Institute of Tropical Medicine, 155, rue Nationale, Antwerp The subject chosen for discussion is Diseases of the Blood and Affections of the Digestive Tract Further particulars may be had from the secretary general Dr G Brohée, 64, rue de la Concorde, Brussels

United Hospitals Festival Choir

More than fifty London hospitals are taking part in this choir which is to sing Mendelssohn's Elijah, accompanied by the London Symphony Orchestra and conducted by Mr Joseph Krips, in the Albert Hall, on Wednesday, May 30, at 7 30 P M The concert is in aid of the Royal College of Nursing Educational Fund. Tickets may be obtained from Mr Colin H Ratcliffe, the chorus master, 10, Waldegrove Park, Twickenham, Middlesex Some more male voices, particularly tenors, are still needed

The M O.H and Mental Health

This year the National Association for Mental Health is again arranging a course for medical officers of health or their deputies The course, which will be held at the London School of Hygiene, Keppel Street, W C 1, from June 4 to 9, will deal with preventive aspects of mental-health work and with provisions for the mentally handicapped, especially those living in the community who are the responsibility of the local authorities It is hoped to arrange some visits of observation in connection with the course Further particulars may be had from the education department of the association, 39, Queen Anne Street, W 1

Prof W Melville Arnott is visiting Cyprus from March 17 to April 7 on behalf of the British Council

CORRIGENDA *Standardisation of X ray Films*—Our annotation last week should have stated that the committee's recommendations appeared in the *British Journal of Radiology* (1950, 23, 272, 500)

Alkali dissolved Diphtheria Toxoid antitoxin Floccules—In this article by Mr J H Mason (March 3) the units of antitoxin per ml of serum before immunisation in each of the first three members of the institute staff who were immunised should have been given as <0 005

Treatment of Burns in Large Numbers—In our account of the discussion of this subject by the Royal Society of Medicine (*Lancet*, Feb 24, p 449) remarks were wrongly attributed to Surgeon Captain S G Rainsford In fact Captain Rainsford said that he thought that the present neglect of antisera was unwise

Births, Marriages, and Deaths

BIRTHS

BORRIE.—On March 4 in Newcastle upon Tyne the wife of Mr John Borrie, M.B E, F R C.S—a son

FISK—On March 6 at Cambridge to Dr Susan Airey, wife of Mr Geoffrey Fisk F R C S—a son

HALLE—On Feb 20, in Sheffield the wife of Dr H M. Halle—a son

MCDONALD—On Feb 24 at Beckenham Kent, the wife of Dr Donald M McDonald—a son

MCGOWAN—On March 7 at Bristol, to Dr Rosalind McG (née Barclay), wife of Dr G K McGowan—a daughter

MANNING—On March 5, in London the wife of Dr Geoffrey C Manning—a son

PRATT—On March 3, at Cambridge the wife of Dr C L G — a daughter

MARRIAGES

MCFADYEAN—CASS—On March 3 at South Ascot, Michael McFadyean, M R.C S, to Barbara Marjorie Joan

DEATHS

DAVIES—On March 5, in Manchester, Evan Sherrah Davie M R C S

DRAPER—On March 3, at Croydon, John Robert Draper, M.B. Camb aged 73

GILL.—On Feb 28, at Oldham Lancs, Harry Gill M B R U.I

HAMER—On March 2, at Chorlton-cum Hardy, Lancs, W Myring Hamer L.M S S A

MONTGOMERY—On March 4, at Chichester Edwin Cecil Montgomery M R.C.S, aged 79

PENNELL.—On March 7 at Findon Sussex Alice Maude O B E M B Lond

TOMLINSON—On March 6 at Hove Percy Stanley T K.B E C B, D S O F R C P aged 66 gastroscopy without any cause for death being discovered, 1 who died of rupture of what was presumed to be a chronic œsophageal abscess, and 1 case of phlegmonous gastritis

The first 2 cases may not have had anything to do with the gastroscopy, but in the absence of any other recognised cause of death they have been included.

One was in a man, aged 30 who was inadvertently allowed to start his lunch immediately on returning to the ward and was found dead in bed half an hour after gastroscopy and forty minutes after the application of an amount of "percaine" which was ' within the normal dosage range." At necropsy no abnormality was found, apart from hyperæmia of the duodenum, no foreign body was found in the bronchial tree

The other patient, a man of 60, who ate lunch two hours after gastroscopy (somewhat sooner than usual) and then went to sleep He was awakened by a severe pain in the right upper abdomen, became collapsed, and on examination showed epigastric rigidity He recovered from the state of collapse, but ten hours after gastroscopy the rigidity was still present and the pulse rate had risen. The abdomen was opened, but no abnormality was found He died twenty two hours after gastroscopy A necropsy was not done The probability is that he had had a coronary thrombosis

The third patient was a woman of 60 who was examined with a Wolf Schindler gastroscope with a rubber finger tip Instrumentation was straightforward, but she developed surgical emphysema of the neck and, despite sulphonamides, died three days later Necropsy showed ' an old chronic para-œsophageal abscess, extending one third the length of the œsophagus, with a perforation into the right pleura. No obvious damage was found in the œsophageal mucosa itself A chronic abscess could hardly have developed within three days, and the case has therefore been classified as one of rupture of a previously existing abscess Nevertheless the occurrence of surgical emphysema is in favour of there having been a small perforation, and if this were the primary lesion it would provide the second instance in this series of a fatal œsophageal perforation associated with the use of the Wolf-Schindler instrument

The case of phlegmonous gastritis occurred in an elderly man with a pyloric carcinoma and complete achlorhydria Twenty-four hours after gastroscopy he had severe epigastric pain and he died a few hours later Necropsy showed an acute phlegmonous gastritis from a 5 mm abrasion in the posterior wall which had become infected by a virulent streptococcus

Reactions to Anæsthetic

In addition to the 5 cases shown in table I a 6th case was also reported, but the corresponding number of gastroscopies was not known The doses given and the types of anæsthetic used are shown in table IV

In all instances, toxic reactions developed within a few minutes In 4 death was clearly due to overdosage, the 5th was not unreasonably attributed by the coroner to idiosyncrasy, and the dosage was similar to that often used without ill effect In the sole case in which recovery took place the dose was not reported.

TABLE IV—REACTIONS TO ANÆSTHETIC

Local anæsthetic	Dose	Result
Cocaine	Gross overdosage with 20% solution	Death
Amethocaine	3 ml. of 1% spray and 2 ml of 2% solution	Death
	12 ml of 2% solution*	Death
"	15 ml of 2% solution	Death
"	12 ml of 4% solution†	Death
	?	Recovery

* A smaller dose had been given at a previous examination without ill effect.

† Dispensed in error as 2% solution.

PREVENTION OF ACCIDENTS

In 1 case perforation followed instrumentation while a Ryle s tube was also down the œsophagus. It is not ordinarily necessary to pass the gastroscope in these circumstances, and any tube already in the œsophagus should clearly be withdrawn first

Contra indications which might have been recognised, accounted for 2 deaths In one case the examiner did not recognise the extent of the patient s kyphosis, and difficulty at the cardia caused a tear at the lower end of the œsophagus, in the other, necropsy revealed a benign stricture of the upper œsophagus, which had been split These experiences reinforce the need for a preliminary examination of the spine and for a barium swallow In cases with a moderately severe degree of kyphosis the Wolf Schindler gastroscope may be passed safely, but the Hermon Taylor instrument is probably much more hazardous Those more familiar with the Wolf Schindler must be specially careful in their selection of cases for the Hermon Taylor gastroscope † A preliminary barium examination will usually demonstrate gross lesions of the œsophagus and cardia, but it will not always do so It did not, in fact, demonstrate the œsophageal stricture which was split, or the carcinoma at the cardia in 1 of the 2 patients in whom a lower œsophageal tear was produced in association with a carcinoma.

Goligher (1948) has suggested that accidents are most likely to happen in the presence of gross osteo arthritis of the cervical spine, and has recommended routine radiography of the neck before endoscopy We have knowledge of the state of the cervical vertebræ in only 4 cases a fatal perforation of the hypopharynx, in which necropsy showed no arthritis, and perforation of the upper œsophagus in 3 patients who recovered Radiography of the neck showed no abnormality in one case, "insignificant ' osteo arthritis of the cervical vertebræ in another, and moderate osteo arthritis of the fifth cervical vertebra in the third. In the absence of stronger evidence we do not feel that routine radiography of the neck would be helpful It is, however, a wise precaution to test the mobility of the neck when considering a gastroscopy

Perforation of the œsophagus could be practically eliminated by giving up the use of the Hermon Taylor gastroscope This instrument has, however, great practical advantages and provides a more certain view of the distal part of the antrum and of the posterior wall of the stomach. For this reason many gastroscopists (including ourselves) are unwilling to abandon its use completely A very great reduction in the number of accidents could still be brought about by giving up the use of the Hermon Taylor gastroscope in women over 50, unless its use is specially indicated, for it is in this group that the great majority of accidents are found. It might also be wise to use the Hermon Taylor instrument only on inpatients, so that treatment can be instituted immediately in the event of perforation

All gastroscopists agree that it is important to maintain flexion of the head and to use the fingers to keep the tip of the gastroscope from pressing against the posterior wall of the pharynx during its passage through the hypopharynx With this technique, Hermon Taylor has personally made several thousand examinations without causing a fatal perforation of the œsophagus On the other hand, several of the reported accidents occurred in the hands of the most experienced examiners, and only a few could be attributed to inexperience In our opinion it is generally safer to reduce the use of the Hermon Taylor instrument in women over 50 to the minimum, rather than to rely on the examiner's skill The possibility of pressure necrosis cannot in all cases be excluded

---

† Since this paper was written the G U Manufacturing Co Ltd. have succeeded in greatly increasing the flexibility of the Hermon Taylor instrument. This modification should diminish the risk of instrumentation.—F A J

The most striking finding is that nearly all the perforations occurred with the use of the Hermon Taylor instrument A death from perforation was reported with the Wolf Schindler gastroscope, and it is possible that a death in the miscellaneous group should have been properly classified as another (see below) To determine the relative risk of the two instruments, it is necessary to know the proportion of examinations made with each of them The estimates made cannot be claimed to be accurate, but neither can it reasonably be held that they are so far out as to account for the different accident-rates It cannot be argued that the lower rate with the Wolf Schindler instrument springs from its being used by more skilful examiners, for, if the comparison is confined to the results reported by the eight gastroscopists who had made more than 500 examinations with each instrument, the same sort of difference is obtained In 14,000 gastroscopies performed by them with the Hermon Taylor gastroscope there were 22 perforations, while in 9000 gastroscopies done with the Wolf Schindler gastroscope there was 1 It must therefore be concluded that the Hermon Taylor instrument is the more dangerous On the other hand, Schindler's claim that his instrument is "completely safe" is shown to be very close to the truth, though it is not entirely substantiated

The blunt metal and the rubber finger tips have been associated with about equal numbers of accidents Both types are in common use, hence there is probably no great difference in the accident rates The blunt rubber (or sponge) tip, which was associated with only 2 accidents, was probably used correspondingly rarely

An interesting observation is that there was no difficulty in instrumentation in 60% of the perforations in which evidence on this point was recorded In fact, the proportion in which there was no difficulty was probably even higher, since it may be presumed that when difficulty was encountered it was more likely to be reported, in view of the end result of the examination Evidently, even with the greatest caution, and if the examination had been abandoned at the slightest abnormal resistance, there would still have been an appreciable number of perforations Accidents were, however, relatively more frequent when there was difficulty, since difficulty is only ordinarily encountered in a small proportion of gastroscopies

Analysis by sex and age of the patient leads to an important finding It has been recognised for some time that the risk is greater in middle aged and elderly women, but the survey demonstrates the very great differences involved If the proportion of examinations made in each age and sex subgroup at one clinic are typical of the whole survey—and gastroscopists who have been asked agree that they are not far out—it can be concluded that the risk in women aged more than 50 is some nine or ten times that in men aged more than 50 and that in younger women, and thirty times that in younger men. The relative risks may be even greater, because many gastroscopists have been accustomed to using the Wolf Schindler instrument in old women, thereby decreasing the risk of perforation

TABLE III—PERFORATION OF ŒSOPHAGUS AND ASSOCIATED ÆTIOLOGICAL FACTORS *

Proportion of gastroscopies	Ætiological factor		No of cases	No of deaths

* Including 4 cases with 2 deaths excluded from table I.

† Based on 898 gastroscopies done by one examiner

No figure has been obtained of the number of examinations made in different clinical conditions, hence it is not possible to compare with much confidence the accident rates in ulcer, carcinoma, and other conditions. Nevertheless it is unlikely that gastroscopy was performed in patients with carcinoma as often as in those with ulcer, and the number of perforations associated with carcinoma must be considered high The perforation was twice directly related to the growth, which had in these instances extended up into the œsophagus, in the remaining cases the lesions were independent. A possible explanation is the association of both carcinoma and perforation with an atrophic mucosa, and it is notable that the main pathological lesion in the stomach was described as "atrophic gastritis" in 6 other instances, and specially that 2 of these were cases of pernicious anæmia, a condition which can relatively seldom have been examined gastroscopically A higher proportion of the carcinoma patients than of the others examined would, admittedly, have been elderly women, and this alone may account for the findings On the other hand, it may well be that it is the frequent occurrence of an atrophic mucosa (in the œsophagus) which makes both elderly women and carcinoma patients specially vulnerable

Perforation of Stomach

After perforation of the œsophagus the next most common accident was perforation of the stomach, though it was responsible for only 1 death This accident used to be common when the rubber sponge tip was in general use (Schindler 1949), but it has become rare since The type of tip used is known in only 5 of the 9 cases in this series, the rubber sponge tip was used in 3 of these, and, in view of the rarity with which it is used, this is consistent with the belief that the rubber sponge tip predisposes to gastric perforation

Hæmorrhage

Little attention has been paid to the incidence of hæmorrhage following gastroscopy, doubtless because of the difficulty of distinguishing between hæmorrhage produced by the instrument and that occurring coincidentally In all, 7 cases were reported, including 2 in which 1 oz of blood was vomited shortly after the examination Slight hæmorrhage of this order may well have occurred on other occasions without being recorded in the series On the other hand, of the 2 deaths, 1 was due to a hæmorrhage which occurred the day after gastroscopy in a patient with hepatolienal fibrosis and may not have been due to instrumentation We have gastroscoped patients less than twenty four hours aft a profuse hæmorrhage and have often performed gastroscopies three or four days afterwards without producin any untoward result Though it would be natural t suppose that hæmorrhage was an appreciable risk of th examination, experience indicates that major hæmorrhag is remarkable for its rarity

Miscellaneous Complications

The 4 miscellaneous cases recorded in table I consiste of 2 patients who died within twenty four hours o jejunal ulcer not otherwise clearly demonstrated. In the small group of patients who bleed repeatedly and have not had a chronic ulcer demonstrated previously, gastroscopy may be of great value in defining the site of the bleeding and determining the need for surgery. In patients with unexplained hæmatemeses, gastroscopy within three to ten days of the hæmorrhage may demonstrate a rapidly healing acute ulcer. However, routine gastroscopy after hæmatemesis to demonstrate such ulcers is not justifiable; gastroscopy soon after hæmatemesis merely to save radiology should not be encouraged. Whether or not gastroscopy assists in the indication for operation in duodenal ulcer remains to be worked out; in such cases it is only justified as part of a planned research. Hermon Taylor (personal communication) has suggested that jejunal ulcers are particularly likely to develop after gastro-enterostomy in those cases in which a duodenal ulcer is associated with increased rugosity of the gastric mucosa. In our view generalised changes in the appearance of the gastric mucosa which have been supposed to indicate gastritis of various kinds are not consistently associated with symptoms. We do not regard the diagnosis of such cases of gastritis as a profitable use of gastroscopy—at least not until further evidence has been provided of their clinical significance.

When it is necessary to check the healing of gastric ulcers gastroscopically to relieve an overburdened X-ray department, it seems advisable to use the Wolf-Schindler gastroscope.

Gastroscopy has a limited but very useful sphere in the practical management of patients with gastric diseases, and the gastroscope still remains a valuable research instrument. Gastroscopy should not be regarded as a final diagnostic method, but the information it provides should be assessed with the clinical picture and other investigations.

SUMMARY AND CONCLUSIONS

The risks associated with gastroscopy have been assessed by means of a questionary sent to forty gastroscopists.

Altogether 75 accidents with 32 deaths were reported, following 49,000 gastroscopies; a further 5 accidents with 3 deaths were reported, but the corresponding number of gastroscopies was not known.

54—i.e., two thirds—of the accidents were perforations of the œsophagus, the great majority of which were in the upper part. Nearly all the perforations of the œsophagus followed the use of the Hermon Taylor gastroscope.‡ Most of them occurred in women over 50 and the risk in this age and sex group is estimated to be nine or ten times that in men aged more than 50 and in younger women, and thirty times that in younger men. It is recommended that the Wolf-Schindler gastroscope should be used routinely for gastroscopy in elderly women and in all outpatients.

An appreciable number of accidents have occurred with both the blunt metal and the rubber finger tips; insufficient evidence has been obtained to determine which is the safer.

Since the introduction of penicillin a considerable proportion of patients with œsophageal perforations have recovered on medical treatment. It is reasonable to treat mild cases conservatively in the first instance but perforation of the lower œsophagus and cases in which a gross leak is apparent should be treated by immediate suture.

Perforation of the stomach has been rare following the abandonment of the rubber sponge tip; when it occurs it may be treated medically.

26 reactions to the anæsthetic were reported, 5 of which were fatal. Of the deaths 4 are attributable to overdosage. 4 ml. of 2% amethocaine should be the maximum used as a local surface anæsthetic.

The indications for gastroscopy are discussed.

We wish to record our thanks for the coöperation of all the gastroscopists who replied to our inquiries. We realise that it is easier to ask questions than to answer them, and we are therefore very grateful for the information and advice, which was often given in great detail, and for the expressions of opinion, which we found most helpful.

ACCIDENTAL PERFORATION DURING GASTROSCOPY

T. H. Boon
M.D. Durh., M.R.C.P.
PHYSICIAN, ROYAL VICTORIA INFIRMARY, NEWCASTLE UPON TYNE

In carrying out nearly 4000 gastroscopies in the past thirteen years I have had 5 mishaps attributable to passing the instrument. Of these gastroscopies 3000 are included in a combined series published in the accompanying paper by Avery Jones and his associates. My mishaps include 4 of gastric perforation and 1 of damage to the posterior wall at the pharyngo-œsophageal junction. All the cases, particularly the gastric perforations, presented an undramatic picture so unlike what one would expect from a perforated viscus as to seem to justify a detailed description for the guidance of those who have not yet encountered such complications.

CASE-RECORDS

Case 1.—A woman, aged 47, was admitted to hospital with symptoms suggesting gastric carcinoma; for six months she had had weakness, loss of weight, anorexia, and vague upper abdominal discomfort. General examination and a barium meal revealed no abnormality. A gruel test-meal showed achlorhydria, and there was moderate hypochromic anæmia. Occult blood was absent from the stools. I was asked to perform a gastroscopy to exclude carcinoma.

Gastroscopy.—The gastroscope was passed easily and without any sensation of resistance at the cardia or elsewhere. I was at that time relatively inexperienced, and I tried repeatedly to inflate the stomach and make the mucosa visible, but I was unsuccessful and withdrew the gastroscope. The patient then complained of upper abdominal discomfort, and examination revealed abdominal distension and loss of hepatic dullness. Perforation of the stomach had evidently taken place, but the patient's general condition was not serious. There was little or no rigidity, and a house-surgeon with moderate experience of surgical emergencies doubted the diagnosis on general inspection of the patient.

Operation.—A perforation in the upper posterior part of the stomach near the greater curve was found and sutured. The gastric mucosa was seen to be atrophic. Recovery was uneventful.

Case 2.—A woman, aged 58, had six months' history of upper abdominal pain, relieved by 'Maclean's powder,' with poor appetite and loss of weight. A barium meal showed irregularity and probably thickening of the greater curvature of the stomach, and a gruel test-meal showed no free hydrochloric acid.

Gastroscopy.—I had no difficulty in passing the gastroscope, but after the insertion of a little air I saw omentum, which proved that perforation had occurred. Examination of the abdomen showed some general tenderness but far short of the usual board-like rigidity following perforation of a peptic ulcer. The patient was examined by a surgeon with considerable experience of surgical emergencies who was not entirely satisfied with the diagnosis until radiography demonstrated gas beneath both cupolæ of the diaphragm.

---

‡ See footnote p 649

as a cause of the perforation, and with tight instrumentation, particularly in short-necked patients, the examination should be concluded quickly

Accidents other than perforation of the œsophagus are very rare, but, nevertheless, some of them are readily preventable Abandonment of the rubber sponge tip practically eliminates perforation of the stomach Schindler (1949) maintains that the rubber finger tip is the only safe tip to use, but the experience of this survey provides no conclusive reason for preferring it to the blunt metal tip The rubber finger tip may act as a dilator and so make instrumentation easier when difficulty is encountered in passing the gastroscope through the pharyngo œsophageal sphincter, but many gastroscopists prefer the blunt metal tip in the straightforward case, and on the evidence available it is not necessary to discourage its use

Deaths under anæsthesia can be almost eliminated by strict limitation of the dose of local anæsthetic 4 ml. of 2% amethocaine hydrochloride should be regarded as the maximum to be administered Attention to this rule would have prevented 4 of 5 deaths under anæsthesia In our experience it is seldom necessary to use more than 2 ml., an additional 2 ml is required only when the first dose has been swallowed too rapidly

Sensitivity and toxic reactions to amethocaine hydrochloride have been studied by Jackson (1949), who makes the following recommendations about prophylactic measures

(1) A barbiturate should be given by mouth in preoperative preparation—e g, phenobarbitone gr 3 (0 2 g), or 'Sodium amytal' or nembutal gr 1½ (0 1 g) 40 minutes before gastroscopy

(2) An amethocaine pastille gr 1 (65 mg) should be given to the patient to suck 30 minutes before gastroscopy

(3) Amethocaine, when used for surface analgesia, should have adrenaline, 1 in 1000 solution, added in a proportion of 4 to 1 by volume, and the total dose of amethocaine should not exceed 4 ml of a 2% solution (80 mg) or the corresponding amount of a more dilute solution

(4) Application with a laryngeal spray should be avoided, since it can easily lead to overdosage

(5) Amethocaine should never be applied to an inflamed, traumatised, or highly vascular epithelial surface

(6) Amethocaine should be avoided in patients giving a history of allergy or in severely debilitated or cachectic persons

Though some gastroscopists find that an amethocaine pastille is adequate, our own experience leads us to prefer 2% solution of amethocaine hydrochloride We have no experience of adding adrenaline and have so far not found it necessary with the limited amount of amethocaine that has been used If a reaction develops, an unobstructed airway should be secured as quickly as possible with an endotracheal tube, and convulsions should be controlled by the intravenous administration of a rapidly acting barbiturate—e g, sodium thiopentone—an ampoule of which should be kept in the clinic According to Jackson (1949) 0 5 g is usually sufficient

TREATMENT

It is difficult to make accurate comparisons of the results of different treatments from the sort of material which has been collected in this survey, and the difficulty has been increased by the fact that part of the series occurred before the introduction of penicillin Since penicillin has been available we have records of 22 patients who were treated conservatively and 6 who were treated by immediate suture Of the former, 5 died, and of the latter, 2 These figures cannot be compared directly, for the types of case in the two groups are probably not comparable For example, there were 2 lower œsophageal perforations in the immediate suture group and none in the conservatively treated group Some of the fatal cases which were treated medically were so treated because the patient's condition did not permit surgical intervention, and others were so mild that surgery was never considered Again, as has been mentioned, mild cases which resolved are less likely to have been reported than fatal cases, hence the fatality rate is likely to be overestimated It is clear, however, that in a considerable proportion of cases the patients recovered on conservative treatment, including some in which the lesion resolved without drainage despite the initial presence of surgical emphysema All that can be concluded is that cases which have mild symptoms and are diagnosed early may reasonably be treated conservatively It is, on the other hand, the consensus of opinion that immediate suture should be undertaken for perforations in the lower œsophagus and when there is evidence of a gross leak The need for early treatment makes it desirable that all patients should be examined three or four hours after gastroscopy, outpatients should be detained for this period and then given instructions to report immediately if they develop a severe sore throat or difficulty in swallowing When there is doubt, radiography of the chest and neck will usually demonstrate the presence of air outside the œsophagus if a perforation is present

Perforation of the stomach during gastroscopy is quite a different condition from that occurring spontaneously, the essential difference being that the stomach is empty when the perforation is produced instrumentally These cases are eminently suitable for medical treatment, in fact, if laparotomy is carried out it will not infrequently be impossible to find the perforation The literature contains 4 such cases (Schindler 1945, Berk 1946, Chamberlin 1947, Lichstein and Wharton 1948) and a 5th, with recovery, occurred in this series Of the gastric perforations in the present series, 3 were treated medically and 5 had laparotomy, all recovered The method of treatment of the patient who died is not known

INDICATIONS FOR GASTROSCOPY

Owing to the definite risk attached to gastroscopy it is important that the indication for each examination should be clearly defined Gastroscopy is particularly useful when there is a disparity between the clinical history and the radiological findings. In patients in whom radiography reveals no abnormality of the stomach, but who nevertheless have symptoms suggesting peptic ulcer or neoplasm, gastroscopy may reveal an organic lesion It is not uncommon to find gastric ulcers which have escaped recognition previously, but the number of carcinomas so discovered is small, however, when a carcinoma is discovered, the case is usually early

Gastroscopy is also of value when an unusual gastric radiological appearance has been demonstrated which does not tally with the clinical picture The deformity may be found to have no intrinsic pathology, what is apparently a large symptomless ulcer high up on the lesser curve may turn out to be a diverticulum of the stomach, a suspected neoplasm may not be confirmed, and laparotomy may be saved Considerable caution must be exercised with distal pyloric defects and, even if the gastroscopy does not confirm the radiological findings, the patient must still be kept under observation and be re examined radiologically Caution must again be observed in assessing the malignancy or innocence of gastric ulcers Gastroscopy will demonstrate that certain ulcers are clearly malignant and others clearly simple, but there is an intermediate group in which it is very hard to be certain, and further observations are needed If the radiological appearance clearly suggests a simple ulcer, gastroscopy is not needed as a routine unless the ulcer fails to heal In patients with gross radiological appearance of neoplasm, little is gained by gastroscopy

In patients with dyspepsia following gastro enterostomy or partial gastrectomy, gastroscopy may define a junal ulcer not otherwise clearly demonstrated In the nall group of patients who bleed repeatedly and have ot had a chronic ulcer demonstrated previously, gastro copy may be of great value in defining the site of the leeding and determining the need for surgery In patients ith unexplained hæmatemeses, gastroscopy within hree to ten days of the hæmorrhage may demonstrate rapidly healing acute ulcer However, routine gastro copy after hæmatemesis to demonstrate such ulcers is ot justifiable, gastroscopy soon after hæmatemesis merely to save radiology should not be encouraged. Whether or not gastroscopy assists in the indication for operation in duodenal ulcer remains to be worked out, n such cases it is only justified as part of a planned research Hermon Taylor (personal communication) has suggested that jejunal ulcers are particularly likely to develop after gastro enterostomy in those cases in which a duodenal ulcer is associated with increased rugosity of the gastric mucosa In our view generalised changes in the appearance of the gastric mucosa which have been supposed to indicate gastritis of various kinds are not consistently associated with symptoms We do not regard the diagnosis of such cases of gastritis as a profitable use of gastroscopy—at least not until further evidence has been provided of their clinical significance

When it is necessary to check the healing of gastric ulcers gastroscopically to relieve an overburdened X ray department, it seems advisable to use the Wolf Schindler gastroscope

Gastroscopy has a limited but very useful sphere in the practical management of patients with gastric diseases, and the gastroscope still remains a valuable research instrument Gastroscopy should not be regarded as a final diagnostic method, but the information it provides should be assessed with the clinical picture and other investigations

SUMMARY AND CONCLUSIONS

The risks associated with gastroscopy have been assessed by means of a questionary sent to forty gastroscopists

Altogether 75 accidents with 32 deaths were reported, following 49,000 gastroscopies, a further 5 accidents with 3 deaths were reported, but the corresponding number of gastroscopies was not known

54—i e, two thirds—of the accidents were perforations of the œsophagus, the great majority of which were in the upper part Nearly all the perforations of the œsophagus followed the use of the Hermon Taylor gastroscope ‡ Most of them occurred in women over 50 and the risk in this age and sex group is estimated to be nine or ten times that in men aged more than 50 and in younger women, and thirty times that in younger men It is recommended that the Wolf Schindler gastroscope should be used routinely for gastroscopy in elderly women and in all outpatients

An appreciable number of accidents have occurred with both the blunt metal and the rubber finger tips, insufficient evidence has been obtained to determine which is the safer

Since the introduction of penicillin a considerable proportion of patients with œsophageal perforations have recovered on medical treatment It is reasonable to treat mild cases conservatively in the first instance, but perforation of the lower œsophagus and cases in which a gross leak is apparent should be treated by immediate suture

Perforation of the stomach has been rare following the abandonment of the rubber sponge tip, when it occurs it may be treated medically

6 reactions to the anæsthetic were reported, 5 of which were fatal Of the deaths, 4 are attributable to over dosage 4 ml of 2% amethocaine should be the maximum used as a local surface anæsthetic

The indications for gastroscopy are discussed

We wish to record our thanks for the coöperation of all the gastroscopists who replied to our inquiries We realise that it is easier to ask questions than to answer them, and we are therefore very grateful for the information and advice, which was often given in great detail, and for the expressions of opinion, which we found most helpful

ACCIDENTAL PERFORATION DURING GASTROSCOPY

T H Boon
M D Durh, M R C P

PHYSICIAN, ROYAL VICTORIA INFIRMARY NEWCASTLE UPON TYNE

In carrying out nearly 4000 gastroscopies in the past thirteen years I have had 5 mishaps attributable to passing the instrument Of these gastroscopies 3000 are included in a combined series published in the accompanying paper by Avery Jones and his associates My mishaps include 4 of gastric perforation and 1 of damage to the posterior wall at the pharyngo œsophageal junction All the cases, particularly the gastric perforations, presented an undramatic picture so unlike what one would expect from a perforated viscus as to seem to justify a detailed description for the guidance of those who have not yet encountered such complications

CASE RECORDS

Case 1 —A woman, aged 47, was admitted to hospital with symptoms suggesting gastric carcinoma for six months she had had weakness, loss of weight, anorexia and vague upper abdominal discomfort General examination and a barium meal revealed no abnormality A gruel test-meal showed achlorhydria, and there was moderate hypochromic anæmia. Occult blood was absent from the stools I was asked to perform a gastroscopy to exclude carcinoma

Gastroscopy —The gastroscope was passed easily and without any sensation of resistance at the cardia or elsewhere I was at that time relatively inexperienced, and I tried repeatedly to inflate the stomach and make the mucosa visible, but I was unsuccessful and withdrew the gastroscope The patient then complained of upper abdominal discomfort, and examination revealed abdominal distension and loss of hepatic dullness Perforation of the stomach had evidently taken place, but the patient's general condition was not serious There was little or no rigidity, and a house surgeon with moderate experience of surgical emergencies doubted the diagnosis on general inspection of the patient

Operation —A perforation in the upper posterior part of the stomach near the greater curve was found and sutured The gastric mucosa was seen to be atrophic Recovery was uneventful

Case 2 —A woman, aged 58, had six months' history of upper abdominal pain, relieved by Maclean's powder,' with poor appetite and loss of weight A barium meal showed irregularity and probably thickening of the greater curvature of the stomach, and a gruel test-meal showed no free hydrochloric acid

Gastroscopy —I had no difficulty in passing the gastroscope, but after the insertion of a little air I saw omentum, which proved that perforation had occurred Examination of the abdomen showed some general tenderness but far short of the usual board like rigidity following perforation of a peptic ulcer The patient was examined by a surgeon with considerable experience of surgical emergencies, who was not entirely satisfied with the diagnosis until radiography demonstrated gas beneath both cupolæ of the diaphragm

---

‡ See footnote p 649

Operation —A perforation was found high up on the posterior wall near the greater curvature The stomach wall was atrophic Gall stones were present Recovery was uneventful, apart from some postoperative pulmonary collapse, which ultimately cleared well

Case 3 —A man, aged 75, was extensively investigated for hypochromic anæmia without obvious nutritional cause All investigations having proved negative, I was asked to gastroscope him to exclude carcinoma or other intermittently bleeding gastric lesion

Gastroscopy —The patient was somewhat uncoöperative, but the gastroscope was passed without any feeling of obstruction or unusual difficulty The assistant was unskilled in dealing with a difficult patient at gastroscopy, and the patient soon got completely out of position At the initial view the gastric mucosa could not be seen, nor could an illuminated field be detected. It was presumed that this was due to the patient's change of posture, and after repeated unsuccessful efforts had been made to correct it in difficult circumstances the instrument was withdrawn The patient's condition at the end of the examination gave no cause for concern, and he did not complain of any pain Since the field had not been detected, it was considered remotely possible that injury might have occurred, and instructions were given for the patient to be closely watched

Operation —Ten hours after gastroscopy he began to complain of upper abdominal pain, and upper abdominal tenderness was detected The presence of gas beneath the diaphragm was established by radiography and laparotomy was performed The perforation was found high up on the posterior wall near the greater curve, and this was sutured Unfortunately this patient developed fibrillation after operation and died three days later of acute pulmonary congestion

Case 4 —A woman, aged 68, gave a long gastric history, and a barium meal showed possible prepyloric carcinoma

Gastroscopy —The patient was coöperative, and the gastroscope passed without difficulty The initial view showed that the instrument was in the stomach and that the optic was somewhat obscured by mucus The instrument was therefore partly withdrawn to wipe it on the posterior wall at the cardia It was then reinserted without any difficulty, but after the introduction of a little air omentum was seen, showing that perforation had taken place The patient complained of no abdominal pain whatever, and the general condition was entirely satisfactory A Ryle's tube was immediately introduced into the stomach and half hourly suction instituted She was seen an hour later by a senior surgeon of considerable experience, who saw her lying comfortably in bed with a pulse rate of 84 and a normal temperature, stating that she had no abdominal pain While awaiting my arrival he expressed doubt about my diagnosis but had no doubt whatever when complete loss of liver dullness was demonstrated

Treatment—The patient was kept in Fowler's position, and hourly aspiration of the stomach continued Fluids were administered intravenously Sulphathiazole was included in the intravenous drip, and penicillin administered intramuscularly The patient remained completely comfortable without any abdominal rigidity or tenderness The highest temperature reached in the next two days was 99°F, and the pulse rate never rose above 90 After forty eight hours the intravenous medication and aspiration were discontinued, and fluid was administered by mouth Recovery was uneventful

Case 5 —A woman, aged 58, had had gastric symptoms for several years A barium meal suggested an ulcer, which might be malignant, in the prepyloric area

Gastroscopy was done with a little preliminary difficulty in passing the pharyngo œsophageal junction. The patient returned to the ward without any suspicion of damage from the examination Next morning her pulse rate was 100, and temperature 102°F, and she complained of some stiffness and soreness of the neck Examination showed a little tenderness in the mid cervical region on both sides Damage to the pharynx was suspected and radiography of the neck showed a bubble of air behind the pharyngo œsophageal junction

Treatment —With sulphathiazole by mouth and penicillin injections, the patient made an uneventful recovery

COMMENTS

All the aforesaid complications took place after the gastroscope had been passed without unusual difficulty In 3 cases of gastric perforation subjected to operation it was noted that the mucosa was atrophic, which may have been a factor in the perforation The clinical picture in all the complications was undramatic and quite unlike what one would expect from a perforated viscus This is understandable since the patient was premedicated with atropine and morphine or with 'Opoidine' and scopolamine, and the stomach was emptied immediately before the instrument was passed, so that there was no food residue or gastric juice to soil and irritate the peritoneum

The perforation in the 3 cases subjected to operation was in a situation difficult of access to the surgeon Such cases seem to be ideal for medical treatment in that the diagnosis is certain, the stomach is empty at the time of perforation, and the peritoneum cannot be soiled by food. Leakage from a high perforation of the stomach is also unlikely to recur in a patient in Fowler's position

The cases reported here illustrate the ease with which a perforation may be caused at gastroscopy, the lack of serious symptoms immediately after the event, and the desirability of instituting medical treatment without delay when even a slight suspicion of perforation exists

GENERAL ANÆSTHESIA FOR GASTROSCOPY

J C Goligher H L Thornton
Ch M Edin, F R C S M.R C S, D A
ASSISTANT SURGEON ANÆSTHETIST
ST MARY'S HOSPITAL, LONDON

Until comparatively recently, like most other gastroscopists, we have performed almost all our gastroscopies under local analgesia with amethocaine ('Decicain') supplemented by heavy premedication with 'Omnopon' and scopolamine or barbiturates With some patients, particularly frail elderly subjects, this technique has yielded excellent results, the instrument being easily and painlessly passed, and well tolerated whilst in situ, a few of the patients have indeed fallen asleep during the examination ! More often there has been a certain amount of discomfort, either during introduction or subsequently, due to pressure on the gum, to the extended position of the head, or to the inflation of the stomach, and in some cases this has made the gastroscopy a distinctly unpleasant experience It must also be recorded that in a small proportion of the cases referred for gastroscopy—about 1 in 30—nervousness and lack of cooperation on the part of the patient have prevented the passage of the instrument and the attempt at examination under local analgesia has had to be abandoned Altogether it can fairly be stated that gastroscopy under local analgesia is an investigation that few patients relish or are readily willing to have repeated on them

The only reason why local analgesia has been tolerated, despite its obvious imperfections, is that it has been held to be much safer than any form of general anæsthesia for this purpose , but with the recent advances in general anæsthetic technique we have felt that there are now good grounds for challenging this contention During the last eighteen months or so we have been experimenting with several methods of administering general anæsthesia for gastroscopy and œsophagoscopy and have eventually arrived at a technique which we are satisfied is thoroughly practicable and possesses significant advantages over purely local analgesia In this paper we shall describe our experiences with general anæsthesia for these forms of endoscopy, particularly gastroscopy

METHODS TRIED

General Anæsthesia Alone —We have had a very limited experience of thiopentone alone for gastroscopy and œsophagoscopy, but found it unsatisfactory because, n order to produce anæsthesia deep enough to abolish all sensation in the pharynx and give complete relaxation of the cricopharyngeal constrictor, it was necessary to push the dose to dangerous levels We had also considered the use of 1% bromethol ('Avertin') intravenously, with which one of us had already had considerable experience for maxillofacial surgery, as described by Thornton and Rowbotham (1945), but, in view of the one unexplained fatality encountered in the series of cases which formed the basis of that communication, we decided to seek a safer alternative

General Anæsthesia and Local Analgesia Combined—We next tried a combined thiopentone and local analgesia technique, it being hoped that the reduction of sensation in the pharynx produced by the local application would lessen the amount of general anæsthetic required The local analgesia was achieved by the patients' preliminary sucking of amethocaine tablets and by the application of amethocaine solution by syringe or applicator to the oral and laryngeal parts of the pharynx This method was certainly more successful, the amount of thiopentone needed being somewhat less, but to secure sufficient muscular relaxation and quiescence for easy endoscopy still necessitated the administration of what we regarded as dangerously depressant doses of thiopentone

General Anæsthesia and Local Analgesia Assisted by Relaxant Drugs—It was not until we supplemented general anæsthesia and local analgesia with relaxant drugs, using a technique similar to that described by Scurr (1950) to provide reliable muscular and sphincteric relaxation that we felt we had a really practicable and efficient method. So successful indeed was the addition of the relaxant that we thought the local analgesic might without disadvantage be omitted, but we soon came to the conclusion that a full topical analgesia was always a valuable adjunct in that it helped to reduce the quantities of thiopentone and relaxing drug needed

It is this threefold method of general anæsthesia and local analgesia supplemented by a relaxant drug that we chose to elaborate and will describe in detail Before doing so, one other technical question might be discussed, and that is the advisability or otherwise of carrying out laryngotracheal intubation The advantage of intubation is that it provides a free airway and allows of easy artificial respiration by rhythmic pressure on the anæsthetic bag, if such should become necessary On the other hand, if a tube is to be tolerated by the larynx and trachea a somewhat deeper plane of anæsthesia must be obtained The presence of the anæsthetic tube extending from the nasopharynx across the oropharynx to the larynx is also a slight impediment during the passage of the gastroscope or œsophagoscope, though less so than might be anticipated Our main reason for not using a tube, however, was that we feared it might increase the risk of injury to the posterior wall of the pharynx by forcing the cricoid cartilage and the endoscope backwards against the cervical spine, and in actual practice we found intubation to be unnecessary

TECHNIQUE OF COMBINED GENERAL ANÆSTHESIA AND LOCAL ANALGESIA SUPPLEMENTED BY RELAXANTS

Premedication—Omnopon and scopolamine is administered hypodermically $1^{1}/_{4}$ hours before the endoscopy in an average dosage of omnopon gr $^{1}/_{3}$, scopolamine gr $^{1}/_{150}$ for a healthy adult Appropriate adjustments are made for extremes of age and weight Tab decicain gr 1 is given 1 hour preoperatively and 30 minutes preoperatively, the patient being instructed to let the tablets dissolve in the mouth as slowly as possible

Topical analgesia is obtained 10 minutes before endoscopy, using 2% amethocaine A total volume of 4 ml of the solution is divided between a galleypot and a Macintosh's laryngeal spray The patient is supported in a sitting position, the tongue, wrapped in a gauze swab, is gently and fully retracted with the operator's left hand The fauces are lightly sprayed with amethocaine After an interval of about a minute to allow this to take effect the analgesic solution is applied to each pyriform fossa in turn with dental cotton rolls held in curved laryngeal forceps The process is repeated twice on each side, the analgesic solution on the dental roll being held steadily in contact with the base of the pyriform fossa for 30 seconds The tongue traction is relaxed between each manœuvre or as often as the patient's comfort demands The patient is now lowered into the recumbent position and the head positioned for laryngoscopy The solution remaining in the spray is introduced between the vocal cords under direct vision with a Macintosh's curved laryngoscope

The patient is now turned on his left side and supported in the position for gastroscopy with the left arm extended on a padded board

General Anæsthesia Combined with Myoneural Block—Thiopentone 5% is now injected into a convenient vein in the extended arm until the patient falls asleep After allowing enough time for the thiopentone to take effect, and noting that respiration is adequate and unobstructed, the thiopentone syringe is detached from the needle and a second syringe charged with gallamine triethiodide ('Flaxedil') substituted Flaxedil is injected in divided doses of 0 5 ml., with pauses to allow each dose to take full effect, until full relaxation is obtained, at which time respiration will have become predominantly diaphragmatic No attempt is made to pass the gastroscope until this stage is reached, when a change back to thiopentone is made Once the gastroscope is in place a Denis Browne hook conveying a stream of oxygen is hooked into the angle of the mouth on the right side, and further thiopentone is administered intermittently throughout the examination, as required

We aim at maintaining an adequate and even respiratory exchange throughout the endoscopy, with complete absence of reflex response to the passage of the instrument An average total dosage of each drug is flaxedil 60–80 mg, thiopentone 0 5–0 75 g We seldom find it necessary to repeat the administration of flaxedil once the change to thiopentone has been made

At the conclusion of the examination the patient is left lying on the left side, and an oral airway is inserted He is not allowed to return to the ward until we are satisfied that the reflexes are returning, that the airway is free, and that the respiratory excursion is adequate to maintain a good colour when the patient is breathing atmospheric air Only in a few cases has it been considered necessary to administer oxygen after the examination has been concluded, and then only for the space of 10–15 minutes By the divided dose method of administering flaxedil we have avoided the accidental overdosage which would result in diaphragmatic paralysis and necessitate the use of neostigmine after the operation

DISCUSSION OF RESULTS

At first the combined general anæsthetic and local analgesic technique with relaxants was reserved for the more apprehensive patients on whom œsophagoscopy or gastroscopy had already been unsuccessfully attempted under local analgesia alone or who were deemed unlikely to submit to examination with that technique, but, encouraged by the effectiveness and apparent safety of the threefold method, we were soon using it as a routine for these forms of endoscopy We have now performed 42 œsophagoscopies and 112 gastroscopies in this way without fatality or serious accident The method has had both advantages and disadvantages which we shall now briefly discuss

Ease of Introduction and Comfort of Patient

Introduction of the gastroscope or œsophagoscope under the combined anæsthetic technique was always very much easier than under local analgesia alone, even in the most cooperative patients, because the neck muscles were always completely relaxed and spasm of the cricopharyngeal sphincter was eliminated The usual precautions, however, were observed in passing the instrument, the utmost gentleness being exercised throughout In the gastroscopies, special care was taken to maintain the point of the instrument in the midline and prevent it falling into either pyriform fossa, and also to press it forwards against the base of the tongue and avoid dangerous impingement on the pharyngeal wall, and this forward manipulation was much more easily carried out in an anæsthetised than in a conscious patient In no case was it found impossible to introduce the instrument We anticipated that the complete bodily relaxation produced by the general anæsthetic might make maintenance of the patient's lateral position for gastroscopy more difficult, but this actually proved no problem, and in fact no additional assistance was required over and above the two nurses or dressers normally employed by us during a gastroscopic examination The patients, of course, have had no discomfort during the investigation and no recollection of the event afterwards, though they may have complained of slight soreness of the throat for a few hours or a day or so So far as the patients' sensations were concerned, therefore, the method may be looked upon as having been 100% successful

Respiratory Difficulties

It will be appreciated that the presence of the gastroscope or œsophagoscope in the pharynx pushing the tongue forward is helpful in maintaining an unobstructed airway, and we have had no troubles due to falling back of the tongue Another possible cause of respiratory obstruction is laryngeal spasm, but thanks partly to the combined use of local analgesia diminishing the sensibility of the pharynx and the larynx, and partly to the relaxant drug employed, this seldom occurred In the 3 cases so complicated, the spasm was easily overcome by increasing the dose of the flaxedil A third source of respiratory trouble is temporary apnœa due to overdosage of thiopentone and the relaxant One of the advantages of the threefold technique that we employ is that the dosage of the general anæsthetic and relaxant usually does not need to be pushed to the point of producing respiratory arrest in order to secure adequate anæsthesia for the endoscopy, but temporary apnœa has occurred in 8 of our patients This has not caused alarm, for, owing to the relaxation of the laryngeal sphincter, it has been found possible to maintain an unimpeded respiratory excursion by rhythmic pressure on the lower thorax by the anæsthetist without interfering with the course of the gastroscopy or œsophagoscopy—and indeed without the knowledge of the endoscopist[1] But if this proved insufficient it would be an easy matter to withdraw the instrument and carry out laryngotracheal intubation We have always arranged for the instruments necessary for this manœuvre to be at hand during gastroscopy or œsophagoscopy under general anæsthesia, though so far we have not had occasion to use them

Risk of Injury Due to Completely Anæsthetic Condition of Pharynx and Œsophagus

The striking ease of introduction of the gastroscope under this combined general anæsthetic technique has already been mentioned, and any risk of injury to the pharynx or œsophagus due to difficulty in negotiating a spastic cricopharyngeus is certainly eliminated However it is notorious that postcricoid perforation during gastroscopy or œsophagoscopy may occur in cases in which the passage of the instrument was attended by no difficulty whatsoever, and probably the main factor in its production is compression of the posterior pharyngeal or œsophageal wall between the shaft or point of the instrument and the prominent extended cervical spine It might be argued that this would be more likely in a completely anæsthetic patient such as is provided by our technique than in one being examined under local analgesia alone, who by virtue of some remaining sensation might feel pain if unusual pressure were exerted and might thereby warn the endoscopist before injury were produced We very much doubt the validity of this argument, because neither of our only two cases of postcricoid pharyngo-œsophageal perforation due to gastroscopy under local analgesia had any special pain during the examination to indicate that an injury had been produced But, apart from its manifest unreliability as a safeguard against injury in the forms of endoscopy now being discussed we think that regulation of the gentleness of an endoscopist's manipulations by the amount of pain produced should be condemned in principle In our view endoscopy should always be conducted in such a way that the patient cannot suffer any pain at all, and we see no reason why the endoscopist should be any less gentle when working with a general anæsthetic technique instead of local analgesia alone Indeed, so far as gastroscopy and œsophagoscopy are concerned, general anæsthesia and relaxant drugs, by producing complete paralysis of the cricopharyngeal sphincter and neck and jaw muscles, enable the examiner to gauge more accurately the resistance which the point of the instrument is encountering on the posterior pharyngeal wall and thereby to avoid the application of undue force to this dangerous area As for excessive pressure of the shaft of the instrument, when in position, on the cervical spine due to over extension of the head under general anæsthesia, this need not occur if an experienced assistant is controlling the movement of the head during the examination

As the accompanying paper by Avery Jones et al. indicates, the risks of gastroscopy are slight and a very large series of cases is required to reveal them in their correct proportions The number of gastroscopies and œsophagoscopies performed by us with the general anæsthetic technique just described is relatively small, and many more cases would need to be examined in this way to provide conclusive proof of the safety of the method This additional experience we are in the process of acquiring We see no reason, however, to suppose that the use of a general anæsthetic technique *per se* should add to the risks of endoscopy any more than suitable general anæsthesia adds to the hazards of the numerous operations in otorhinolaryngology and dental surgery for which it is regularly employed

CONCLUSIONS

Our experience demonstrates that gastroscopy and œsophagoscopy can be very satisfactorily performed under combined local analgesia and general anæsthesia assisted by relaxant drugs, apparently without increased risk This technique eliminates all discomfort for the patient, it also provides much easier working conditions for the endoscopist than does local analgesia alone, and it abolishes failure to introduce the instrument On the other hand, vigilance is required to deal promptly with any respiratory difficulties and avoid danger from this source Necessitating as it does the presence of an experienced anæsthetist, the method is undoubtedly more elaborate and slightly more time consuming than a purely local analgesic technique For that reason it may not commend itself to those working in large gastroscopic clinics where many of the cases gastroscoped may be outpatients Though such workers may think it inconvenient for routine use, we are confident that they will find it indispensable for their more nervous patients who might not otherwise be successfully gastroscoped at all. To explore fully the safety of the method we propose to continue to use it for all our gastroscopies and œsophagoscopies.

We wish to express our indebtedness to Dr R M. Mackenzie and Dr C M Parrott, anæsthetic registrars, for administering the anæsthetics to some of the cases which form the basis of this report

USE OF HIGH-FREQUENCY ULTRASONIC WAVES FOR DETECTING CHANGES OF TEXTURE IN LIVING TISSUES

J J WILD
M.A M.B Camb
AT DEPARTMENT OF SURGERY, UNIVERSITY OF MINNESOTA

DONALD NEAL
B Aero Engng
U S NAVAL RESERVE, AT WOLD CHAMBERLAIN NAVAL AIR STATION

MINNEAPOLIS, MINNESOTA

THE development of high frequency ultrasonic apparatus by the U S Navy during the late war provided an opportunity to make some pilot experiments at 15 megacycles on biological tissues The experiments (Wild 1950) were directed towards the measurement and the detection of changes in the texture of biological tissues Further pilot experiments are described below

PRINCIPLE

Electrical energy can be converted into sound energy by means of crystals that show the piezo electric phenomenon Sound waves of very high frequency—far above the audible range—can be obtained in this way If this sound energy is generated in pulses, the pulses of sound waves travel out from the crystal in a manner analogous to that of sound propagated in the larynx. These pulses of sound energy are reflected as echoes from interfaces—i e , surfaces at which density changes—in a manner analogous to that of an echo returning from a mountain

The echoes of the pulses of sound from interfaces can be multiple if enough power is put into the pulses to drive them through multiple interfaces. Thus, if it were possible to penetrate a series of mountains lying one behind the other in the path of a shout, then echoes would be obtained from each successive mountain as the shout passed on through air to the next mountain, and so on

The echoes returning from a mountain at which a shout is directed are picked up by the human ear The piezo electric crystal, in addition to propagating sound-waves, can also ' hear " sound waves Thus one crystal could generate pulses of sound waves while another received the pulses, and the time could be measured for the passage of the sound waves through permeable media placed between the sender and the receiver Or the same crystal can both transmit and receive the echoes—the method used in the experiments described here

MEASUREMENT

Two measurements can be made (1) the time taken for a pulse to travel through a given permeable medium and to return to the source of propagation of the pulse, and (2) the " strength " of the echo or echoes returning from interfaces in the path of the propagated pulses

If we use the analogy of the shout at a mountain face, the time could be measured for the shout to leave the larynx, hit the mountain face, and return to the ear In addition, the ' strength " of the returning echo could be appreciated A loud shout would return a more powerful echo than a less loud shout Again, if it were possible to penetrate a series of mountains of equal thickness and density spaced equally apart, it would be possible to detect a series of successive echoes returned from each successive mountain as the shout passed through The energy of the shout would gradually be lost as it passed through each successive mountain, hence the power of the echoes would gradually fall off until no energy would be left to give an echo However, the *times* to pass through the various " layers " of air and mountain would be a fixed quantity, no matter what the strength of the returning echoes

The value of the two measurements can be summarised as follows if the shouter were blind he could detect both the presence of a mountain in front of him and the nearness of the mountain to him This echo-ranging is used by bats, and by blind people employing electronic apparatus Further, if the speed of sound were known in air and in the various mountain masses traversed by the shout, it would be possible to determine the thickness of the mountains and their distances apart

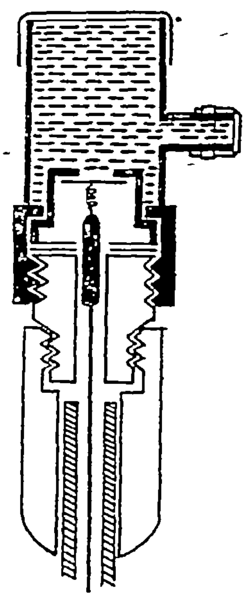

Fig 1—Ultrasonoscope consisting of a chamber filled with water so as to exclude air-bubbles Over one end is stretched a rubber membrane and at the opposite end a piezo-electric crystal is mounted in contact with the water The instrument can be held in the hand in any desired position and applied to the skin in the same manner as the end piece of a stethoscope.

FREQUENCY

The question of frequency of the ultrasonic energy is of vital importance theoretically, and is analogous to the resolution of an optical microscope The higher the frequency the better is the differentiation of texture changes Ludwig (1949) has recommended a frequency of 2 5 mega cycles for the detection of gall stones buried in the muscles of dogs Considerably higher frequencies were considered to be necessary for the differentiation of biological tissues. However, the higher the frequency for a given power output the less is the penetration of the pulses , so a compromise must be worked out for a given application

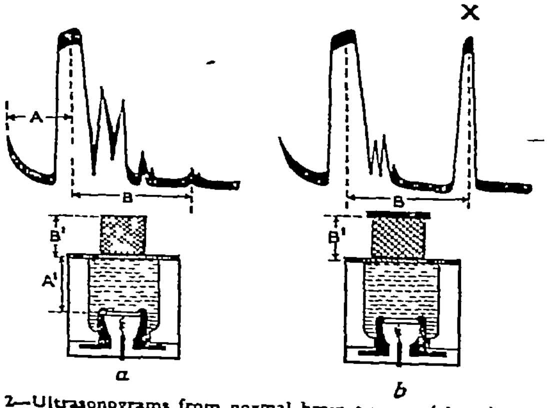

Fig 2—Ultrasonograms from normal brain tissue (a) without aluminium sheet interposed (b) with aluminium sheet interposed A time taken for ultrasonic wave to travel distance A (from crystal to rubber membrane and back) , B time taken for ultrasonic wave to travel distance B (from rubber membrane to far side of brain tissue and back)

blastic The bone marrow, obtained by sternal puncture or at necropsy, appeared aplastic or hypoplastic in twenty six patients, marrow hyperplasia was observed in the remaining case, which followed exposure to radium

DIFFERENTIAL DIAGNOSIS FROM ALEUKÆMIC LEUKÆMIA

Cases of aleukæmic leukæmia may present as refractory anæmias of the macrocytic type, without enlargement of the liver, spleen, or lymph nodes (Scott 1939, Hynes 1940, Wintrobe and Mitchell 1940) Superficially these cases may closely simulate aplastic anæmia Usually in aleukæmic leukæmia the peripheral blood contains primitive cells, while the marrow is hypercellular and shows a hiatus leukæmicus This is not invariably so In aleukæmic leukæmia of the lymphatic type the marrow may be acellular Aplastic anæmia and leukæmia are disorders of the growth of blood cells, and possibly they may occur successively in one and the same patient as phases of one and the same illness

In three patients in the present series aplastic anæmia and aleukæmic leukæmia could not at first be clearly differentiated In one patient a few primitive cells were found in the peripheral blood, but the marrow was hypoplastic, although the primitive cells suggested aleukæmic leukæmia, necropsy a year later proved the case to be one of aplastic anæmia Another patient, who showed a similar combination of an acellular marrow, without preponderance of any one cell type, with the presence of scanty primitive cells in the peripheral blood, became frankly leukæmic shortly before death nine months later, and typical leukæmic infiltrations were seen at necropsy Repeated examinations of blood and marrow may therefore be necessary before a diagnosis between these two conditions can be made

ÆTIOLOGY

Wintrobe (1946) has collected the known causes of aplastic anæmia These are first the aromatic hydrocarbons, of which benzene is the most toxic, organic arsenicals, gold compounds, radioactive substances, and X rays Rare causes are mustard gas poisoning, bismuth, mercury, colloidal silver, dinitrophenol, trinitrotoluene, hair dyes, volatile insecticides, and various analgesics Recently tridione has been added to this list (Mackay and Gottstein 1946, Harrison et al 1946), as well as mepacrine (Custer 1946) Apart from these causes there is a large idiopathic group to which twenty four cases in the present series belong All our patients were closely questioned about possible bone marrow toxins, for removal from exposure may increase the slender chances of recovery Only three were exposed to potential marrow poisons—arsenic, lead, and radium This contrasts with the experience of Bomford and Rhoads (1941), who found a high incidence of toxic causes The discrepancy may be due to the fact that our patients were largely drawn from a rural population where industrial hazards are absent

CLINICAL FEATURES

There were fifteen male patients and twelve female The age of onset varied between 5 and 74 years, with an average of 43 years In most cases the disease presented as an insidious refractory anæmia, without other abnormal clinical features Eight patients first complained of purpuric symptoms such as bruising, bleeding from the gums, and menorrhagia In two the first symptoms were those of agranulocytosis The modes of onset in our cases were as follow

Mode of onset		*No of cases*
Insidious anæmia only		15
Anæmia and purpura	3	8
Purpura	5	
Anæmia and agranulocytosis	1	2
Chronic agranulocytosis	1	
Gross splenomegaly anæmia and agranulocytosis		1
Pyrexial illness with anæmia		1

The spleen was palpable in four cases, in one of them splenectomy was performed and a second came to autopsy

A familial incidence was found in only one patient, whose brother also died of aplastic anæmia Four patients gave family histories of other forms of anæmia, diagnosed as pernicious anæmia in two, leukæmia in one, and an unspecified anæmia in one Congenital defects were uncommon, an undescended testis, a second thumb, microcephaly, and a congenital cyst of the kidney The last occurred in the patient whose brother also had had aplastic anæmia, and this was thought to be an example of Fanconi's syndrome—the association of congenital defects and aplastic anæmia in several members of the same family (Fanconi 1927, Dacie and Gilpin 1944) Minor endocrine abnormalities were present in five patients

PROGNOSIS

Of the twenty seven patients seen during this period of 10 years, only two were alive 2 years after it ended A third patient recovered from the disease after it had run a course of 18 months, but died 6 years later from carcinoma of the colon All the rest have died from the disease, more than half within 2 years of the onset Clinically it seems that purpura and agranulocytosis both adversely affect the prognosis Occasionally it is possible to keep patients alive for long periods by blood transfusions In one patient with severe aplastic anæmia repeated transfusions maintained life for 9 years Nevertheless the results are disappointing, particularly in view of the fact that the patients were followed carefully and transfusions were given without stint

SIZE OF RED CELLS

Bomford and Rhoads (1941) stated that the mean corpuscular volume (M C V) in fifty three of their cases of refractory anæmia was 75–120 c µ, with a mean of 98 c µ Daland et al (1946) published data from seventeen cases of aplastic anæmia in a paper on the differentiation of macrocytic anæmias, but their cases were selected to include only those with a M C V greater than 100 c µ We have measurements of red cells in sixteen cases of aplastic anæmia, where the patient had not been transfused within the previous $3^{1}/_{2}$ months

Heparin was used as anticoagulant in determining red cell volumes Red cell diameters were measured by the Price Jones method, using a projection microscope with a high dry lens, as described by Biggs and Macmillan (1948) The dry lens gives diameters about 0 3 µ higher than does the oil immersion lens, owing to optical factors which have been discussed by Gunther (1928) and Mogensen (1938) Our normal values (table I), based on measurement of sixteen controls, are M C V 89 9 c µ ± 0 92, mean corpuscular diameter (M C D) 7 45 µ ± 0 074, and mean corpuscular thickness (M C T)

TABLE I—SIZES OF RED CELLS IN APLASTIC ANÆMIA

Case no	M C V (c µ)	M C D (µ)	S D (µ)	V (%)	Macrocytosis (%)	M C T (µ)
1	97 4	7 93	0 58	7 30	4 8	1 97

16	106 0	8 85	0 81	9 14	31 4	1 71

M C V mean 100 0 μ^3 ± 2 30 M.C.D mean 8 23 µ ± 0 096, M C T mean 1 97 µ ± 0 066, V coefficient of variability

2 07 μ ± 0 034 The figure for macrocytosis indicates the percentage of red cells which are larger than any normally present in the blood. At least half of this unselected series of cases of aplastic anæmia show a considerable macrocytosis The M C V is abnormally high in twelve of the thirteen available figures, the M.C D is abnormally high in fifteen of the sixteen cases, and the means of both are significantly greater than our normal values The increments in M C V and M C D and the variability are smaller in aplastic anæmia than in pernicious anæmia, and, whereas asymmetry is observed in the Price Jones curves from pernicious anæmia, in aplastic anæmia all the curves tend to be symmetrical about the mean No relation was found between the size of the red cells and the severity of the disease, as measured by course and response to treatment, though probably the macrocytosis, like the anæmia, is due to reduction in the frequency of cell division

LIVER FUNCTION

Bomford and Rhoads (1941) reported decreased liver function in some of their cases They used only two tests of hepatic function—the bilirubin excretion test of Harrop and Barron (1930) and the sodium benzoate conversion test of Quick (1933) Higgins et al. (1944) showed that an estimation of the amount of bilirubin, alkaline phosphatase, albumin, and globulin in the plasma from a single sample of blood usually provides as much diagnostic and prognostic information as can be obtained from more elaborate tests of liver function. In table II the results of these biochemical estimations on our cases of aplastic anæmia are compared with the investigation made by Higgins et al (1944) of liver function in normal people and in proven liver disease On these criteria there is no evidence of impairment of liver function in our cases of aplastic anæmia, a fact which is verified by the absence of structural change in the livers at necropsy

TABLE II—LIVER FUNCTION IN APLASTIC ANÆMIA

Plasma constituents	Normal controls (100)	Liver diseases (71)	Aplastic anæmia
Serum bilirubin (mg per 100 ml)	0 5 ± 0 33	8 4 ± 3 46	0 38 ± 0 04 (27)
Alkaline phosphatase (units)	8 0 ± 2 0	33 0 ± 2 52	8 13 ± 0 64 (16)
Total protein (g per 100 ml)	7 1 ± 0 38	6 8 ± 0 12	6 58 ± 0 14 (18)
Albumin (g per 100 ml)	4 6 ± 0 29	3 2 ± 0 09	4 24 ± 0 2 (18)
Globulin (g per 100 ml)	2 2 ± 0 35	3 2 ± 0 13	2 13 ± 0 16 (13)

The figures in parentheses indicate the number of cases

TREATMENT

No treatment has been found to affect the anæmia, with the exception of blood transfusion. All the known hæmatinic drugs were tried without response Massive dosage of liver extract of known potency (intramuscular 'Anahæmin' 200 ml. over 10 days) proved ineffective, as did suprarenal cortical extract (intravenous 'Eucortone' 350 ml. in 6 days) Splenectomy, done in four cases, likewise failed to affect the course of the disease Although the anæmia can usually be controlled by transfusion, and the agranulocytic episodes by the antibiotics, we are usually powerless to alleviate the hæmorrhagic tendency

Where there is no loss of blood, as from purpuric lesions, transfusions of blood at regular intervals have maintained a few patients in fairly good health for long periods One patient received 217 pints of blood in 9 years, the transfusions being given at 3 month intervals Nowadays we prefer to transfuse smaller amounts of blood at shorter intervals—e g, one or two pints of blood a fortnight The patient can thus be treated as an outpatient without interruption of his activities In a few patients the transfused blood seemed to be destroyed faster than normal, although there was no rise in the serum bilirubin level One of these patients had his spleen removed, but this did not improve the state of affairs The skin may become pigmented after repeated transfusions of blood, but we have seen no evidence of visceral drainage, such as occurs in hæmochromatosis

DISCUSSION

The cases described here form one of the groups of anæmias which are refractory to all forms of treatment, and in which blood transfusion alone prolongs life For these cases Bomford and Rhoads (1941) have proposed the terms refractory anæmia, but there are other refractory anæmias, such as some of the acquired hæmolytic anæmias (Fisher 1947) To avoid confusion with these and with the refractory megaloblastic anæmias we prefer the older terms aplastic or aregenerative anæmia (Ehrlich 1888) It is true that in some cases of aregenerative anæmia the bone marrow is cellular, but a cellular marrow is infrequent in our experience Even when it is cellular, the marrow is presumably inactive as regards its function of delivering cells to the peripheral blood, and it is this functional aplasia in cases with histologically cellular marrows which justifies their inclusion in the aplastic anæmia group Chemical toxins, such as benzene, may lead to aplasia or to hyperplasia of the bone marrow (Mallory et al. 1939), and a wide variety of blood pictures has been recorded from such causes (Hunter 1939) In our series toxic causes were rare It is perhaps for this reason that so few hyperplastic marrow pictures were encountered, and that the cases were clinically more homogeneous than those described by Bomford and Rhoads (1941)

The pathological material—i e, that obtained at nine necropsies, the spleens from four patients submitted to splenectomy, and forty seven sternal-marrow smears —has not shown any unusual features apart from bone marrow hypoplasia and the excessive iron pigment deposits which usually follow transfusions of large amounts of blood. The underlying ætiology of aplastic anæmia remains unknown Although Bomford and Rhoads (1941) suggested that impaired liver function may be one of the causal factors, no evidence could be found in our cases that the liver is functionally or structurally affected The macrocytosis which has been shown to be a feature of aplastic anæmia can be simply explained by the retarded mitosis of the erythroblasts, as was demonstrated in pernicious anæmia by Japa (1945)

SUMMARY

The clinical features of twenty seven cases of aplastic anæmia are recorded, and the differential diagnosis from aleukæmic leukæmia is discussed The bone marrow was aplastic or hypoplastic in twenty six cases, hyperplasia was present in only one case Only three patients had been exposed to potential marrow poisons, the remainder falling into the idiopathic group

Macrocytosis is shown to be a feature of aplastic anæmia Liver function tests have revealed no impairment in hepatic function

Repeated blood transfusions have proved to be the only means of prolonging life in aplastic anæmia Nevertheless more than half of the patients died within 2 years

I should like to thank Prof L J Witts for his help in the preparation of this paper and his permission to present cases from his department, and also those members of the departments of medicine and biochemistry who made many of the routine investigations

EFFECT OF A C T H IN ACUTE DERMATOMYOSITIS

M M SUZMAN
M D Durh, M R C P
SENIOR PHYSICIAN
JOHANNESBURG HOSPITAL

J A RUDOLPH
M.B Witwatersrand

IN the United States 'Cortisone' and pituitary adrenocorticotropic hormone (A C T H) have been used with varying degrees of success in the treatment of diseases involving collagen tissue, such as rheumatic fever, acute disseminated lupus erythematosus, scleroderma, and dermatomyositis

DISCUSSION

A C T.H. has been used in seven cases of dermatomyositis

Elkinton et al (1949) report the case of a boy, aged 5 years, who had been critically ill for seven weeks with high fever, generalised cutaneous eruption, and œdema, and who was considered to be moribund with hepatomegaly, polyserositis, cardiac enlargement, and hypertension when A C T.H. therapy was begun. Two short courses of 40–80 mg daily were given, followed by a third course, of 80 mg daily, for four days and 10 mg daily for about twenty days After the first two courses relapses occurred, but after the third course a lasting remission was obtained Symptoms of potassium deficiency developed but were readily controlled by the administration of potassium salts

Two cases of dermatomyositis treated with A C T H are reported by Ragan (1950) In the first case, in which the disease had been present for three years, A C T H 100 mg daily was given for eighteen days, this was followed by improvement for twelve days, when a relapse occurred, In the second case, of two years' duration, A C T H 100 mg daily was given for nine days, and improvement was noted during the first five days of therapy, after which there was a great increase in muscular weakness not due to potassium deficiency, and A.C T.H. therapy had to be stopped In both of these patients the dermatomyositis was chronic, in which respect it differed from that of the present patient and of those of Elkinton et al (1949) and Oppel et al (1950)

Oppel et al (1950) report a case in a man, aged 30, who, in his second attack of acute dermatomyositis, made a prompt and dramatic recovery when treated with A.C T.H. 100 mg daily for two days On the seventh day of treatment, after the daily dosage had gradually been reduced to 25 mg, a relapse occurred, which was promptly controlled by increasing the daily dosage to 100 mg The patient remained free from symptoms for four months after having received almost 4 g of A C T H in fifty three days In the early improvement, the return of symptoms when the dosage of A.C T H was reduced, and the fall in the urinary output of creatine their case resembled the present one, but their daily and total dosages of A C T.H were considerably higher

Thorn et al (1950) report three cases A girl, aged 9 years, who had had dermatomyositis for two months, received A C T.H 740 mg in sixteen days in the dosage of 10–15 mg six hourly Her skin lesions improved, but remarkably her muscular strength did not increase appreciably until she had received additional therapy with testosterone In the second case a girl, aged 6 years, with joint symptoms for two months and severe progressive muscular weakness for one month, necessitating the use of a respirator, received A C T.H. 1560 mg in twenty-eight days in the dosage of 20 mg six hourly Gradual improvement took place, and after three weeks the respirator was dispensed with Supplementary therapy with testosterone was given, and after six months, although the girl had regained her strength, the disease was considered to be still active In the third case, in an adult female, after cortisone 100 mg daily for three weeks had brought about very little improvement in muscular strength, A C T H 25 mg six hourly was followed by slight but more definite improvement These workers express the opinion that A C T H can alter the acute inflammatory and destructive process within the affected muscles, but do not think that a lasting remission is likely to be obtained except with vigorous treatment in the very early cases They advocate the additional use of testosterone for its anabolic effect in restoring muscle function and in controlling the inflammation

We report here the effect of A C T H on a patient who was critically ill with acute dermatomyositis and improved dramatically within a few hours and finally recovered completely

CASE RECORD

A man, aged 38 and weighing 325 lb, who had had rheumatic fever at the age of 11 years, had remained well until Feb 15, 1950, when he developed sore throat, malaise, enlarged tender cervical lymph nodes, catarrhal otitis media, and mild pyrexia, for which intramuscular procaine penicillin 300,000 units daily was given for three days Two weeks later, after having shown slight temporary improvement, the patient complained of undue tiredness, profuse perspiration, and moderate pyrexia A preparation of sulphadiazine, sulphamerazine, and sulphathiazole 1 g four hourly given for three days produced only slight improvement

Six days later the symptoms returned with generalised aches and pains and a temperature of 101°F, no definite abnormal physical signs were detected, and "virus infection" was tentatively diagnosed, and the patient was given 'Aureomycin' 250 mg four hourly for two days, but without relief During the following week pyrexia (99–102°F), profuse sweats, and general aching of the body persisted, and the patient began to experience pain and tenderness of the right wrist and of the muscles of the shoulder girdle Acute rheumatic fever was diagnosed, and sodium salicylate gr 20 four hourly was given for four days, and later aspirin gr 20 two hourly was given for twelve days, but this medication, together with frequent 10 mg doses of 'Heptalgin' and 'Physeptone,' did not reduce the fever or relieve the pains

On March 13, the twenty eighth day from the onset of the illness, a blood count showed Hb 13 3 g per 100 ml, red cells 4,400,000 per c.mm, and leucocytes 8700 per c.mm. (neutrophils 68 5%, lymphocytes 20 5%, monocytes 9 5%, eosinophils 1 5%) The red cells showed diffuse polychromasia, the erythrocyte-sedimentation rate (E S R.) was 45 mm in an hour (Wintrobe) Agglutination tests were negative for *Salmonella typhi O* and H, *S paratyphi A*, *S paratyphi B*, and *S paratyphi C* in the dilution of 1/25, and for *Brucella abortus* and *Br melitensis*, and *Proteus O X 19*, *O X 2*, and *O X 4* in the dilution of 1/50 The streptococcal anti hæmolysin 0 titre was 300 units per ml of serum (normal 0–200) The urine contained no abnormal constituents

On the thirty first day of the illness the patient was given deoxycortone acetate 5 mg intramuscularly and ascorbic acid 1 g intravenously After two injections on consecutive days, this medication was discontinued because of a distinct exacerbation in symptoms The pains in the limbs were intensified, the patient could not move his right arm or hand, and, two days later, there developed swelling of the right wrist and pain and tenderness of the left knee The temperature ranged between 100° and 103°F, pulse rate

84–88, and blood pressure 156/84 mm Hg For the next few days the patient's condition continued to deteriorate and he began to have severe dyspnœa, his neck muscles became stiff and painful causing difficulty in turning his head and both ankles became painful and swollen.

On March 22, the thirty seventh day of the illness, treatment with procaine penicillin 600,000 units twice daily was begun again, and a blood count showed Hb 14 0 g per 100 ml, red cells 4,400,000 per c mm, and leucocytes 16,000 per c mm. (neutrophils 87 0%, lymphocytes 10·5%, monocytes 2 5%) The E S.R. (Wintrobe) was 30 mm in an hour, and the packed cell volume was 42 5% Blood cultures in bile and broth showed no growth. Agglutination tests for the typhoid, brucella, and proteus groups of micro organisms again proved negative The urine contained a large amount of albumin and a large excess of urobilin, but no sugar bile pigments, or acetone, the sediment contained scanty red cells and pus cells, but no casts

Clinical examination at this stage showed a very ill man, extremely weak unable to sit up unaided or to raise his arms from his sides, and hardly able to move his legs He had severe pains in the muscles of his neck, shoulders, and limbs, was perspiring profusely, and had difficulty in breathing and talking There was a complete lack of appetite, he was mentally depressed, and weeping spells were frequent There was swelling of the ankles and wrists, œdema of subcutaneous tissues of the forearm and hands, and rapidly progressing wasting of the arms and legs, involving mostly the deltoid muscles, the outer muscles of the thighs and the small muscles of the hands, with extreme weakness of the grip The skin over the left ankle and right wrist was red, and a fine erythematous maculopapular rash had appeared on the skin of the back The skin had become thickened and firm, offering a greater degree of resistance to the insertion of the hypodermic needles On examination of the chest, extensive moist sounds were heard throughout both lungs posteriorly The heart was enlarged to the left, no murmurs could be heard, and the second aortic sound was not heard The pulse was collapsing in type and the sounds of the peripheral pulsations—so-called "pistol shots'—could be heard on auscultation of the extremities The systolic blood pressure was 120–180 mm Hg, and the diastolic was constantly 0 The liver and spleen were impalpable The deep reflexes were all present and normal

Radiography of the chest revealed gross cardiac enlargement, widening of the superior mediastinum, and diminished transradiancy throughout both lung fields, interpreted as being due to congestive changes Acute dermatomyositis was diagnosed

On March 27 the forty second day of the illness, a blood count showed Hb 11 7 g per 100 ml, red cells 4,100,000 per c.mm, and leucocytes 13,800 per c mm (neutrophils 78%, lymphocytes 20%, monocytes 2%) The serum protein level was 7 g per 100 ml (albumin 2 6 g per 100 ml, globulin 4 4 g per 100 ml., the A/G ratio being 1 1 7) The prothrombin index was 90%, the serum bilirubin level 1 2 mg per 100 ml, thymol turbidity 2 units, and thymol flocculation negative, and the cephalin cholesterol flocculation test gave a one-plus positive reaction The antistreptolysin 0 titre was 200 units (normal maximum 200 units) Cold agglutinins were not detected The urine contained a moderate amount of albumin, no sugar a trace of bile pigment and a moderate excess of urobilin the sediment contained no red cells, pus cells or casts

Biopsy of Skin and Muscle—Dr I. Webster of the South African Institute for Medical Research, reported as follows

Sections of this specimen of skin and muscle biopsy show the presence of a keratotic stratified squamous epithelium in which there is a reduction in the stratum granulosum The rete pegs are irregular and in parts consist of a few layers of cells There is well marked increase in the collagen of the corium and in parts the fibres are swollen and have a necrotic appearance Adnexal structures are present but are widely separated by the connective tissue The muscle fibres are swollen in parts, and in an occasional area the cells have a granular appearance The cross striations are still present, and no evidence of homogenisation, vacuolation or necrosis has been found Although there is no interstitial cellular infiltration in parts there is a slight increase in interstitial connective tissue The histological features suggest one of the collagen disease group, but no definite features of dermatomyositis have been detected

Treatment—Since neither cortisone nor a potent preparation of A C T.H was available, it was thought that the combined administration of a steroid hormone, such as testosterone, with ascorbic acid, might prove effective These two preparations were given once daily for seven days intramuscular testosterone 25 mg daily, followed immediately by intravenous ascorbic acid 1 g Concurrently with this therapy, procaine penicillin 900,000 units was given once daily and intramuscular aneurine chloride 100 mg daily, because of the resemblance of the cardiovascular features to those found in acute vitamin B_1 deficiency

After three days of this medication, there having been no improvement, a course of pregnenolone 100 mg by mouth four hourly was given for five days as additional therapy During this treatment the patient's condition continued to deteriorate rapidly, his temperature remaining between 100° and 103°F with increasing respiratory rate and pulse rate extension of the maculopapular eruption on the back, and progressive muscular paralysis and wasting, with severe pains and tenderness in the muscles and joints necessitating the frequent use of pethidine for its relief, swallowing had begun to become difficult, and the breathing more and more distressed

At this stage, on April 4 when it was considered that the immediate outlook for survival was extremely grave, a substantial supply of A C T H. ('Corticotrophin, Organon) was obtained * The 24-hour urinary excretion of 17 keto steroids was 7 mg, uric acid 0 46 g, preformed creatinine 2 33 g, and creatine 0 56 g The high figure for creatine was regarded as an important diagnostic feature of acute dermatomyositis The blood sodium level was 331 mg per 100 ml, and blood potassium level 20 5 mg per 100 ml A blood count showed Hb 12 1 g per 100 ml, red cells 4 100,000 per c mm., and leucocytes 17,500 per c mm (neutrophils 84%, lymphocytes 7 5%, monocytes 6% eosinophils 0 5%, basophils 1% myelocytes 1%) The red cells showed diffuse polychromasia. The administration of intramuscular A C T H 10 mg six hourly was begun at 6 P M on April 5, 1950, the fifty first day of illness

During that night the patient slept well, and next morning after he had had three doses of 10 mg each, his condition had improved dramatically His temperature had fallen to 98 6°F, and his pulse rate and respiratory rate were lower He felt very much better the pain and tenderness in the muscles and joints had diminished appreciably, and he could raise his arms above his head and sit up unaided His breathing was less distressed, dysphagia had disappeared, and his appetite had improved to the extent that he enjoyed a hearty breakfast for the first time since the onset of his illness During the first 24 hours of treatment the urinary excretion of preformed creatinine and of creatine showed a pronounced decrease to 1 17 g and 0 14 g respectively

After 48 hours the temperature fell to subnormal levels, there was an appreciable further increase in muscular strength, the swelling of the wrists had disappeared, and all pain and tenderness in the muscles and joints had gone The patient was now bright and cheerful, whereas previously he had been despondent depressed and highly emotional, with frequent weeping spells

On the fourth day of treatment, his condition generally was found to have improved still further with the return of still greater muscular power The blood pressure was 150/0, with "pistol shots still to be heard at the extremities

On the seventh day of treatment a blood count showed Hb 12 8 g per 100 ml, red cells 4,400,000 per c mm and leucocytes 31,000 per c mm (neutrophils 81%, lymphocytes 11% monocytes 3%, neutrophil myelocytes 5%) The E S R (Wintrobe) had diminished to 16 mm. in an hour with a packed cell volume of 41% The blood sodium and blood potassium levels were unchanged at 331 mg and 20 mg respectively per 100 ml the blood protein level was 5 5 g per 100 ml (albumin 2 8 and globulin 2 7 g per 100 ml making the A/G ratio 1 1) The fasting blood sugar level was 120 mg per 100 ml On examination of the lungs scanty basal râles were still heard but the breathing had become normal The skin rash on the back had faded appreciably, was less erythematous, and had begun to show a faint brownish pigmentation Two days later the lungs were completely free from moist sounds, and the patient's strength had so improved that he felt he could get out of advantage in skin grafting and the transfer of skin flaps and pedicles

---

* The potency of this preparation which was furnished through the courtesy of Dr W J Tindall of Organon Laboratories Ltd London was stated to be equivalent to that of Lala (Armour)

(4) More extensive surgery is possible at one operation when bleeding is no longer a deciding factor—e g , extensive skin grafts to face and neck

(5) The postoperative recovery of many patients seems to be considerably improved (see below)

Operations on the head and neck and body wall, particularly when it is necessary to graft large raw areas or to raise extensive skin flaps, where considerable hæmorrhage is expected and the use of tourniquets impossible, are obvious fields in which the low pressure technique has its greatest application In these cases the dry bed and absence of bleeding and reactionary œdema are a great advantage Skin flaps do not seem to suffer from a deficient circulation when blood pressure is low and the field ischæmic Indeed they appear clinically to be much improved The congestive cyanosis produced by a high blood pressure with a relatively restricted venous return is absent, and the flap seems to benefit thereby

Where distortion of skin and subcutaneous tissues is of no significance to the surgeon, an extensive infiltration with adrenaline and saline solution often produces an almost complete absence of bleeding In many fields of surgery this technique is satisfactory, but in plastic surgery it is unsatisfactory Hæmostasis obtained with adrenaline and saline solution in muscle is poor, but with postural ischæmia it is good In bone, where there is no other method of controlling bleeding except by tourniquet, it is particularly successful

Subcutaneous injections of adrenaline cause an intense constriction and emptying of blood vessels which makes effective clotting more difficult, particularly since these vessels retract when cut When the vessels relax, there may be a postoperative reactionary hæmorrhage, particularly if at the same time the blood pressure is rising or raised After hexamethonium bromide the vessels are dilated, lie open on the cut surface, and become thrombosed during the operation They constrict on to the clot during recovery, and for these reasons postoperative reactionary hæmorrhage is considered to be less likely than when local vasoconstrictors are used

Emphasis must be placed again on the need for elevation of the site of operation to produce adequate ischæmia The area will become pallid as ischæmia develops, while the more dependent parts, such as the feet, become congested and their veins stand out prominently Less advantage is gained in perineal surgery with the legs elevated in the lithotomy position, for the blood drains into this area from the legs Although the blood pressure may be reasonably low, there is still some considerable ooze A Trendelenburg tilt can be used to elevate the perineum and so reduce the oozing, but it tends to raise the blood pressure

Similarly, in lower abdominal operations the Trendelenburg position, in the absence of vasomotor control, so assists the venous return to the heart that the blood pressure is maintained at a figure high enough to have a noticeable effect on the pelvic organs There is here a conflict of principle between the drainage of the part concerned and the effect on the blood pressure In such cases it has been found that the horizontal position is the most satisfactory , for, if an adequate drop of blood pressure can be obtained in this position, or by the help of lowered legs only, operations in and around the pelvis receive considerable assistance Where hypotension and postural ischæmia are only partially satisfactory it is observed that hæmostasis is nevertheless more quickly and satisfactorily obtained

TECHNIQUE AND MANAGEMENT

Little change has been made in the method and technique of anæsthesia reported previously (Enderby 1950) A muscle relaxant drug is now added to the thiopentone for induction to assist intubation when this is indicated, and such drugs do on occasion assist the autonomic ganglionic blocking of the methonium compounds We tend to use intratracheal anæsthesia more widely than before because of our anxiety to maintain a perfect airway under all conditions Maintenance of anæsthesia is by nitrous oxide and oxygen (2 1) in a semi closed circle absorber assisted occasionally by very small doses of ether, but intermittent thiopentone is the basal anæsthetic Cyclopropane is avoided Indeed there does not seem to be need for agents stronger than nitrous oxide in the usual conduct of these cases The Gordh needle, which is always used, is placed in the most convenient vein, usually on the dorsum of the foot for most operations on the head and neck Even with steep reverse Trendelenburg positions of 30–40° the circulation time, as judged by the injection of agents via this needle, is not prolonged

The initial dose of hexamethonium bromide varies with age and the preoperative blood pressure, the normal young adult receiving 50 mg , the effects of drug and posture are assessed in 3 minutes Patients over 40 years of age receive 30–40 mg , and hypertensives, arteriosclerotics, and those over 60 years of age begin with 20 mg It is becoming clear that the response to hexamethonium bromide falls roughly into two categories the young healthy patient shows an increase of pulse rate to 120–140 per min and the postural hypotension is not profound , and the older patient, particularly if hypertensive and arteriosclerotic, shows little rise of pulse rate, indeed occasionally a bradycardia, and the postural hypotension is profound The first group requires considerably more hexamethonium bromide and the maintenance of *extreme* posture (e g , up to 40° reverse Trendelenburg) to preserve surgically useful hypotension The second group may require an increase of an initially small dose of hexamethonium bromide but moderate posture (e.g., 5–10° reverse Trendelenburg) suffices to maintain an adequate hypotension, which when once stabilised at the optimum shows little tendency to alter for $^1/_2$–1 hour Naturally this latter group is much easier to manage when once stabilised, *although initially the response* to hexamethonium bromide is very dramatic, and needs most careful observation

All hypotensive patients must have the undivided attention of the anæsthetist Repeated blood pressure and pulse estimations are necessary, together with a careful observation of the site of operation Much valuable information is provided by this, and an estimate of blood pressure can be obtained from the degree and nature of the bleeding Only arterial bleeding is observed when there is an optimal hypotension and postural ischæmia When postural ischæmia is poor, venous bleeding is increased Colour changes and the state of the peripheral circulation must be carefully watched It is unpardonable to leave these patients unattended for even short periods If constant attention is impossible, this method should not be used

The measurement of blood pressure requires some practice and the adoption of a *standard method for all cases* There is wide variation between the figures obtained by auscultation, palpation, and oscillometry Palpation was used when *auscultation* failed, as it so often did when the pressure was low, and after practice it became possible to palpate to 40 mm *Hg* More recently oscillometry has been used *in* all cases it is the most convenient method under theatre conditions It should be borne in mind that this method *gives readings 5–10 mm Hg higher* than does any other

With the patient prone the legs can be dropped by a combination of the jack knife and reverse Trendelenburg positions This effectively reduces blood pressure, but unfortunately causes pressure on the abdominal veins As a result operations *in the* spinal canal are accompanied by troublesome bleeding from the dural veins, which are prominent. When the patient is supine, elevating the gall bladder bridge causes considerable hypotension. The fall is increased when the abdominal incision releases the negative pressure normally transmitted to the upper abdomen by the respiratory excursion. All these factors influence the blood pressure by affecting the venous return to the heart.

Positive pressure respiration, either assisted or controlled, is another powerful factor affecting blood pressure, the importance of which has been shown by Sarnoff et al (1950) in dogs under total spinal sympathetic block. The absence of respiratory movements and a raised pulmonary pressure diminish the venous return to the heart, and they thus have the same effect as posture.

Reversion from the inclined to a more horizontal position raises the blood pressure considerably, but it is our policy to prevent any sudden rise of more than 15–20 mm Hg. This may be accomplished on return to the ward by elevating the head end of the bed and raising the patient on extra pillows. Thus a slow return to normal blood pressure is ensured—an essential factor in promoting coagulation in tissue planes. Blood pressure must be higher than 70 mm Hg and rising slowly before the patient leaves the theatre. In the hypotensive state danger arising from respiratory obstruction is very much greater, hence the airway must be most carefully preserved until consciousness enables full control to be exercised by the patient.

RESULTS

Hæmorrhage

With a hypotension of 55–65 mm Hg assisted by postural ischæmia bleeding is insignificant, and it should not be necessary to produce more profound falls. Where posture cannot be used to full advantage, bleeding is noticeable even though the blood pressure is low, and in those positions which cause back pressure on the venous system bleeding may be troublesome. Increasing experience enables us to maintain the optimal pressure in most patients, and to obtain the full benefits of postural ischæmia in a wider field of surgery.

In this series 170 cases have been conducted at pressures of 55–80 mm Hg and have been entirely satisfactory except occasionally when it has been impossible to use postural ischæmia. 55 of our patients have been maintained at 80–100 mm Hg. These were not so good as in the previous group, but were nevertheless helpful. This latter figure includes many of the original cases in which pentamethonium iodide was used. The remaining 25 are the earliest records when the action of pentamethonium iodide was under investigation and the effect on bleeding was often small or insignificant.

The postoperative return of blood pressure is slow, and normal levels are not reached for several hours. This is important in the prevention of reactionary hæmorrhage. In this series one patient had a small reactionary hæmorrhage soon after return to bed, and it was believed that owing to inadequate posture the blood pressure rose too quickly. In two other patients there has been postoperative bleeding, but there were also complicating factors. One patient had a large abdominal flap attached to the arm, and on recovery she was restless, and disturbed both the attachment and the dressings. In the other patient, who had undergone excision of the head and neck of a femur, an injection of adrenaline and saline solution had been given into the subcutaneous tissues. Local vasoconstrictors often raise the blood pressure by a generalised action on the peripheral vessels, and their local action may make reactionary hæmorrhage likely, hence they should not be used.

The sudden loss of even a small quantity of blood after vasomotor control has been removed leads to a considerable fall of blood pressure. It is dramatic how the pressure can be restored immediately by intravenous replacement of an equivalent volume. Where bleeding is anticipated because of the position of the patient or of other factors, it is important to have intravenous therapy to hand. Saline solution or dextrose saline solution, &c, may be used as an immediate measure, but blood loss must be replaced eventually by blood.

Vomiting

Careful records made by the recovery ward sister and nurses at Queen Victoria Hospital, East Grinstead, have shown the vomiting rate in the first 12–24 hours in an unselected series of 1000 normal anæsthetic cases to be 38%. In 100 cases in which hexamethonium bromide or pentamethonium iodide had been given, vomiting occurred in 18%. This number is too small to be statistically significant, but the figures are encouraging. Further, it is observed clinically that the vomiting of many patients who have undergone a long series of operations can be greatly diminished, and sometimes entirely prevented, by the action of these drugs. This effect is more definite during the first three hours after their administration, and few patients vomited during this time, and of those who did vomit many did so only after ‘Omnopon’. (It is impossible to analyse further the above figures of 1000 cases into pre-omnopon and post-omnopon vomiting.) The action of these drugs on gastric secretion and mobility (Kay and Smith 1950) is probably responsible for the lower rate of vomiting, and perhaps also for the condition sometimes observed where for one or two days after operation patients show little desire for food, whereas normally they enjoy a good appetite.

Duration of Operation

It has been possible to shorten many intranasal and antral operations to 5–15 minutes. In other regions operations lasting up to 225 minutes have been successfully completed with no apparent ill effects from the low pressure. It is not recommended that this technique be used for such lengthy periods. Before this method is used, operating time should be reduced by more rapid surgery or by more assistance, for it has long been realised that postoperative morbidity depends directly on the time taken to operate. In very lengthy operations it is unwise, in the present state of our knowledge, to add this largely unknown factor of hypotension. A plea is thus made for rapid surgery under these better operating conditions in the knowledge that for short periods controlled hypotension is a safe possibility, of great material assistance to both patient and surgeon.

Age

The limits have been from 11 to 78 years. The best hypotension and ischæmia are more difficult to obtain in the young than in the aged patient. Aged patients should be treated with the greatest caution, with the pressure not lower than 75 mm Hg, nor should the operation time be prolonged. The coronary circulation in aged patients may be poor. Dr D A Robertson has made electrocardiograms of a few of these patients when hypotensive, and he has not found any evidence of coronary ischæmia. It is considered that this technique should not be used if signs of coronary arterial insufficiency are already present.

Other Findings

A few patients have complained of sleepiness for 24–48 hours after operation. This is apparently due to the drug and not to the low pressure. It has been observed where the pressure was not lower than 90–100 mm Hg, and has been absent in those with considerably lower pressures. Further, it has not been observed in hypotensive patients who have not had hexamethonium bromide.

Headaches are rarely complained of.

One patient complained of difficulty in reading for 24 hours after operation, an effect probably due to the action of hexamethonium bromide on the nervous control of the eye.

advantage in skin grafting and the transfer of skin flaps and pedicles.

(4) More extensive surgery is possible at one operation when bleeding is no longer a deciding factor—e.g., extensive skin grafts to face and neck.

(5) The postoperative recovery of many patients seems to be considerably improved (see below).

Operations on the head and neck and body wall, particularly when it is necessary to graft large raw areas or to raise extensive skin flaps, where considerable hæmorrhage is expected and the use of tourniquets impossible, are obvious fields in which the low pressure technique has its greatest application. In these cases the dry bed and absence of bleeding and reactionary œdema are a great advantage. Skin flaps do not seem to suffer from a deficient circulation when blood pressure is low and the field ischæmic. Indeed they appear clinically to be much improved. The congestive cyanosis produced by a high blood pressure with a relatively restricted venous return is absent, and the flap seems to benefit thereby.

Where distortion of skin and subcutaneous tissues is of no significance to the surgeon, an extensive infiltration with adrenaline and saline solution often produces an almost complete absence of bleeding. In many fields of surgery this technique is satisfactory, but in plastic surgery it is unsatisfactory. Hæmostasis obtained with adrenaline and saline solution in muscle is poor, but with postural ischæmia it is good. In bone, where there is no other method of controlling bleeding except by tourniquet, it is particularly successful.

Subcutaneous injections of adrenaline cause an intense constriction and emptying of blood vessels which makes effective clotting more difficult, particularly since these vessels retract when cut. When the vessels relax, there may be a postoperative reactionary hæmorrhage, particularly if at the same time the blood pressure is rising or raised. After hexamethonium bromide the vessels are dilated, lie open on the cut surface, and become thrombosed during the operation. They constrict on to the clot during recovery, and for these reasons postoperative reactionary hæmorrhage is considered to be less likely than when local vasoconstrictors are used.

Emphasis must be placed again on the need for elevation of the site of operation to produce adequate ischæmia. The area will become pallid as ischæmia develops, while the more dependent parts, such as the feet, become congested and their veins stand out prominently. Less advantage is gained in perineal surgery with the legs elevated in the lithotomy position, for the blood drains into this area from the legs. Although the blood pressure may be reasonably low, there is still some considerable ooze. A Trendelenburg tilt can be used to elevate the perineum and so reduce the oozing, but it tends to raise the blood pressure.

Similarly, in lower abdominal operations the Trendelenburg position, in the absence of vasomotor control, so assists the venous return to the heart that the blood pressure is maintained at a figure high enough to have a noticeable effect on the pelvic organs. There is here a conflict of principle between the drainage of the part concerned and the effect on the blood pressure. In such cases it has been found that the horizontal position is the most satisfactory; for, if an adequate drop of blood pressure can be obtained in this position, or by the help of lowered legs only, operations in and around the pelvis receive considerable assistance. Where hypotension and postural ischæmia are only partially satisfactory it is observed that hæmostasis is nevertheless more quickly and satisfactorily obtained.

TECHNIQUE AND MANAGEMENT

Little change has been made in the method and technique of anæsthesia reported previously (Enderby 1950). A muscle relaxant drug is now added to the thiopentone for induction to assist intubation when this is indicated, and such drugs do on occasion assist the autonomic ganglionic blocking of the methonium compounds. We tend to use intratracheal anæsthesia more widely than before because of our anxiety to maintain a perfect airway under all conditions. Maintenance of anæsthesia is by nitrous oxide and oxygen (2 : 1) in a semi-closed circle absorber assisted occasionally by very small doses of ether, but intermittent thiopentone is the basal anæsthetic. Cyclopropane is avoided. Indeed there does not seem to be need for agents stronger than nitrous oxide in the usual conduct of these cases. The Gordh needle, which is always used, is placed in the most convenient vein, usually on the dorsum of the foot for most operations on the head and neck. Even with steep reverse Trendelenburg positions of 30–40° the circulation time, as judged by the injection of agents via this needle, is not prolonged.

The initial dose of hexamethonium bromide varies with age and the preoperative blood pressure, the normal young adult receiving 50 mg.; the effects of drug and posture are assessed in 3 minutes. Patients over 40 years of age receive 30–40 mg., and hypertensives, arteriosclerotics, and those over 60 years of age begin with 20 mg. It is becoming clear that the response to hexamethonium bromide falls roughly into two categories: the young healthy patient shows an increase of pulse-rate to 120–140 per min. and the postural hypotension is not profound; and the older patient, particularly if hypertensive and arteriosclerotic, shows little rise of pulse-rate, indeed occasionally a bradycardia, and the postural hypotension is profound. The first group requires considerably more hexamethonium bromide and the maintenance of extreme posture (e.g., up to 40° reverse Trendelenburg) to preserve surgically useful hypotension. The second group may require an increase of an initially small dose of hexamethonium bromide but moderate posture (e.g., 5–10° reverse Trendelenburg) suffices to maintain an adequate hypotension, which when once stabilised at the optimum shows little tendency to alter for $^1/_2$–1 hour. Naturally this latter group is much easier to manage when once stabilised, although initially the response to hexamethonium bromide is very dramatic, and needs most careful observation.

All hypotensive patients must have the undivided attention of the anæsthetist. Repeated blood-pressure and pulse estimations are necessary, together with a careful observation of the site of operation. Much valuable information is provided by this, and an estimate of blood-pressure can be obtained from the degree and nature of the bleeding. Only arterial bleeding is observed when there is an optimal hypotension and postural ischæmia. When postural ischæmia is poor, venous bleeding is increased. Colour changes and the state of the peripheral circulation must be carefully watched. It is unpardonable to leave these patients unattended for even short periods. *If constant attention is impossible, this method should not be used.*

The measurement of blood-pressure requires some practice and the adoption of a standard method for all cases. There is wide variation between the figures obtained by auscultation, palpation, and oscillometry. Palpation was used when auscultation failed, as it so often did when the pressure was low, and after practice it became possible to palpate to 40 mm. Hg. More recently oscillometry has been used in all cases; it is the most convenient method under theatre conditions. It should be borne in mind that this method gives *readings 5–10 mm. Hg higher* than does any other.

With the patient prone the legs can be dropped by a combination of the jack-knife and reverse Trendelenburg positions. This effectively reduces blood-pressure, but unfortunately causes pressure on the abdominal veins. As a result operations in the spinal canal are accompanied

Case 6—A married woman aged 44, with very advanced metastatic osseous deposits, began treatment with testosterone propionate 300 mg daily on Dec 1, 1949, and this was reduced to 300 mg on alternate days on Feb 28, 1950 While she was having the daily injections her libido was increased very much

Case 7—A widow, aged 62, with carcinoma of the breast She had a Horner's syndrome and an effusion in the left chest Treatment with 200 mg of testosterone propionate daily was started on Feb 14, 1950 There was general improvement, with a gain in weight of 14 lb, hirsuties, and a husky voice Libido increased after 14 days, and while the patient was having this massive dosage she was bothered by a constant warm irritation of her clitoris She also complained of an increased sensitivity of her right breast The clitoris measured 0·8 cm wide and was bright red By this time she had received 14 2 g in 71 days

Case 8—A widow, aged 63, had cancer-en cuirasse involving the whole of the left breast and osteolytic metastases Therapy with testosterone propionate 200 mg daily was started in May, 1949, and 39 2 g was given in 196 days About a month after the injections began, the patient had sexual cravings She had a slight growth of beard, a low pitched voice, and an enlarged clitoris

Case 9—A married woman aged 44, was treated for $9^1/_2$ months periodically with a total dose of 26 1 g of testosterone propionate She had very widespread metastases from breast carcinoma and later developed a pleural effusion.

At one period after doses of 300 mg and later 100 mg daily of testosterone propionate, totalling 11 5 g in 96 days, her libido was much increased, and intercourse was frequent, but her clitoris was not enlarged

Case 10—A married woman who had the same dosage for about 2 months denied any sexual stimulation, but her reaction to treatment had not been so favourable as in some of the other cases and she still had symptoms of her disease

DISCUSSION

The action of these large doses of testosterone propionate in this small series confirms the earlier findings of numerous workers cited above The inhibitory action claimed by Rubinstein et al. (1940) and Greenblatt (1940) can probably be explained by their use of a small dose Before testosterone was used for metastatic breast carcinoma, large doses were rarely given to women

Perloff (1949) maintains that a genetic factor sets the sexual pattern, and that a hormone develops the organs needed for the sex act and increases their sensitivity to stimulation He states that the increased effect on libido observed in women treated with large amounts of testosterone for breast cancer occurs coincidently with hypertrophy of the clitoris the psychological sexual urge is not primarily increased, but rather the sensitivity of the organ

Any direct psychological effect of the injections received by these patients can be dismissed, because they were all in a poor state of health and some were ignorant of any possible sexual effect of this treatment for cancer Those who knew that they were being given male hormone with probable virilising effects, would not expect an increased stimulation of feminine desire.

In view of the fact that, in the married women, coital frequency was low or normal in their previous state of good health, it is remarkable that, coincident with partial physical improvement with androgen therapy, their sexual appetite should not merely return to its previous level but greatly exceed it

If this increased sexuality is merely due to clitoridal development, it does not explain why in Klein's (1950) rabbits the frequent acceptance of the male only lasted as long as the androgen effect, depending on the method of application, or why it was observed so soon after injection or why it occurred after administration of other steroids—e g, progesterone If the effect is due to clitoridal stimulation and development, one would expect the altered sexual behaviour to last longer It is not unreasonable in view of Klein's observations, to postulate that this effect of testosterone may be in general

In women with Simmonds's disease or Addis disease libido is absent but returns with testoster therapy Possibly androgens may be the normal fa influencing sexual behaviour in both male and fem the added gonadal androgen being responsible for aggressive male sexual behaviour In the female state of receptivity to the male may normally be trolled by adrenal cortical androgens and consider augmented by exogenous androgens In female anı cortical adrenal androgens may fluctuate rhythmic as do œstrogens, and act synergically with their œstrus

So far as I know, there is no definite evidence that does occur, but Lobban (1949) has shown that in the ratio between the width of the zona fasciculata the width of zona reticularis, expressed as percent of the cortex width, excluding the glomerulosa, is able, and, when the cats were divided into groups according to the state of activity of their gonads, there was a characteristic ratio for each group, It was chiefly the variations in width of the reticularis which was responsible for the difference in F/R ratio If such variation in measurable histological ratios can be confirmed, it may well coincide with cyclical variations in output of cortical androgen

SUMMARY

During the treatment of advanced cases of mammary carcinomatosis with large amounts of testosterone propionate a considerable and abnormal increase in sexual desire was recorded in those patients who had shown temporary clinical improvement

These observations confirm those of some other workers on the effect of androgens on sexual behaviour in females and are in accord with the experiments of Klein on animals

It is suggested that sexual behaviour in the female may normally depend more on suprarenal androgens than on œstrogens

I am indebted to the late Dr J P Raban and to Drs S Curwen and R C Tudway for referring cases for treatment, and to the faculty of the Bristol Royal Hospital for their permission to do this work which would not have been possible at least in the early stages, without the very liberal supplies of testosterone propionate kindly provided by Ciba Laboratories Organon Laboratories and British Drug Houses

Greenblatt and Wilcox (1941), using 25–145 mg by implantation in ten women found a definite increase in sexual libido in every patient

As the dosage used in women increased and workers were conscious of the possible effect on libido, more comments on the stimulation of the sexual urge were made

Salmon (1941), who gave 500 mg of testosterone monthly to his patients, reported increased libido during the course of injections and for several weeks after, in many the clitoris was very red and sensitive to touch

Later Greenblatt et al (1942) reported on the effect of testosterone on libido in the female, and deliberately treated fifty five patients, aged 22–53, by implantation of pellets to increase it, 100 mg was the best dose by this method There was a resurgence of libido in nearly all the patients who had previously had sexual desire

After Loeser (1941) had reported a beneficial effect of implants of male hormone in cases of mammary carcinoma, several papers were published, mostly in America, on the effect of androgens on cancer of the breast

Farrow and Woodard (1942), Nathanson (1944), Farrow (1944), Fels (1944), Prudente (1945), and Adair and Herrmann (1946) used gradually increasing doses, but none commented on the effect on libido in a fairly large number of women

Herrmann and Adair (1946), discussing the effect of testosterone on soft-tissue metastases from carcinoma of the breast in six cases, stated that "facial hirsutism, deepening of voice, and acne, and an increase in libido were encountered to a greater or less degree in all the patients" Herrmann et al (1947) said that an increase in libido was noted in some of his patients treated for breast cancer with 100–200 mg of testosterone propionate twice a week or 100 mg three times a week

Abel (1945) reported *on androgenic therapy in malignant* disease of the genitalia in five patients who received 150 mg weekly One of these women, aged 60, who for two years had not had intercourse, was so stimulated that coitus took place twice weekly Similar effects were reported in the other patients

Wyatt (1948), who gave 150 mg twice a week in one case to a total dose of 35 g, made no comment on a sexual effect

Following these rather conflicting reports, Klein (1950) reported some remarkable results after administration of steroid hormones to rabbit does

The spayed doe will not receive the buck unless she has been treated with œstrogens or with other hormones With testosterone, however, a much more dramatic effect was observed than with œstrogens or with progesterone the doe received the buck as many times as possible while the androgen effect lasted When Klein implanted a pellet of testosterone subcutaneously, the doe accepted the male for full coitus six times daily for forty seven days until the implant was absorbed

PRESENT INVESTIGATION

During a study * of the treatment of cases of very advanced metastases from breast cancer with massive doses of testosterone propionate in oil, a similar effect on sexual behaviour has been found

The doses of testosterone propionate varied between 200 and 300 mg daily for several weeks until improvement occurred or the patient was obviously not benefited and was deteriorating rapidly In those in whom clinical improvement was found the doses were gradually reduced in amount and frequency The highest total dose is 60 g and several still under treatment have received over 40 g

CASE RECORDS

Case 1 —A married woman aged 42 had had a radical mastectomy in September, 1946, for carcinoma followed a month later by deep X ray therapy In May, 1949, she had developed multiple and widespread osseous metastases involving all the vertebræ of the lower dorsal and lumbar spine, and also the sacrum both pubic bones, and both ischii The menses remained regular

Treatment was started on Jan 7, 1950 300 mg daily of testosterone propionate being given in oil by intramuscular injection After 52 days her husband reported that for some *while she had lost all her pain and felt* much better, but during the last 14 days she had developed an almost insatiable desire for intercourse Previously she had never been much interested in sex, and on an average intercourse had taken place about once a month, but she now sought sexual gratification at every opportunity For the first time in her life she experienced orgasm

When examined on March 3 she had increased in weight and had a high facial colour and plethora, though there was only a little fine down on her face and chin, and her voice was not much altered Her clitoris was larger than normal, and she had a slight yellowish vaginal discharge There had been no menstrual bleeding since Jan 4 She had received 15 g of testosterone propionate in 52 days Radiography later showed that the bones had healed considerably, with union of the fractures

Case 2 —A married woman, aged 51, had had a radical mastectomy in December, 1948, for scirrhous carcinoma, followed by deep X ray therapy Osseous metastases had, however, developed in ribs and vertebræ

Therapy was started on Jan 17, 1950, with 200 mg of testosterone propionate daily while in hospital She was discharged from hospital on Feb 25, and when seen a month later she could walk with reasonable comfort When questioned about any alteration in libido, she said that before her operation, when normally fit, she had usually had intercourse about twice weekly, but during her illness it became infrequent On her return from hospital her desire had so increased that she sought intercourse four or five times a week. She had had a hysterectomy sixteen years before, and orgasm had been rare, but now she obtained full sexual satisfaction. There was also a slight vaginal discharge, and vulval secretions were increased

On examination the clitoris protruded from its prepuce and measured 1 5 cm long and 1 cm wide The total dose received by this time was 14 g of testosterone propionate

Case 3 —An unmarried woman, aged 42, had had a radical mastectomy for carcinoma in April, 1940 She later developed sciatica, and radiography showed destructive lesions in both ilia and in some vertebræ

Treatment with testosterone propionate 300 mg daily was started in November, 1948 The pain disappeared and the patient returned to work She remained fit and free from any recurrence, and by April, 1950, she had received 38 7 g of testosterone propionate

When asked, she said that, since her general health had improved, she had noticed very definite sexual cravings, which she had rigidly to control She had a sensation of fullness in both groins and was conscious of a continuous warm feeling in the clitoris The glans clitoris was 1 cm. wide and protruded when the labia were parted Other signs of virilism were considerable, with a growth of beard, acne, and a deep low pitched voice

Case 4 —An unmarried woman, aged 53, had had a left radical mastectomy for carcinoma of the breast in November, 1946, followed by deep X ray therapy In September, 1948, she developed a pleural effusion and metastases in the right lung

Injections of 300 mg of testosterone propionate daily were started in November, 1948 By December 1949, the pleural effusion had completely cleared and her general condition was excellent By the end of March, 1950, she had received 52 6 g of testosterone propionate She said that while having the daily doses of 300 mg she had noticed a sexual craving which she found difficult to understand and which was unusual for her She denied any sensation in her clitoris, but this was 0 9 cm wide

Case 5 —A married woman aged 37, had had a left radical mastectomy in 1942 In October 1948 two large metastases in the lungs were found

A bilateral oöphorectomy was done on Nov 8 1949, and injections of testosterone propionate 300 mg daily were started on Nov 21, 1949 this dose being later reduced to 200 mg on alternate days The patient's general health improved, with a gain in weight of 10 lb, but there was little change in the X ray appearances in the chest With increased libido, intercourse increased in frequency from once to twice a week. Her clitoris was enlarged, the glans was 0 9 cm wide and bright red Her voice was very husky but there was only a little hair on her upper lip She had then received 15.7 g of testosterone propionate

* This study was conducted during the tenure of a grant for a laboratory technician from the British Empire Cancer Campaign

THE LANCET

LONDON SATURDAY, MARCH 24, 1951

On April 8

THE Census of 1951 is everybody's story, and nobody's. It belongs to everyone, because each of us contributes a brick to its immense structure, and to nobody, because not one of those bricks carries a name and address. The Census is one of the few human institutions that bring benefit to every citizen and harm to none. In its modern shape the information that it reveals tells us not only where we stand, in number and proportion, but also in what direction we are moving. At the present time our nation urgently needs this information, for the last numbering of the people took place as long ago as 1931. The intervention of the blitz ten years ago tore a great hole in our knowledge about population, life, and death, and the gap could only be loosely plugged by more or less inspired guesswork.

The broad general uses of a census are obvious enough, but it is just as well that we should count the blessings we derive from it. The national population returns, and their breakdown into the smallest units of local government, form the only accurate basis for the daily business of living. Some of the figures could be obtained by other means, but the Census is the most economical way of doing the job. Its records are props to trade at every level, and they are indispensable for the administrative activities of local authorities. The shifting pattern of modern industry and the disrupting forces of war have brought important regional changes in the distribution of our population, how great the changes are we can only estimate today, and we need the Census to give exact information to help in the convenient siting of industry and in town and country planning. Again, the vital statistics which are compiled from the Census returns—the tale of birth, death, marriage, and fertility rates—are the stuff out of which national calculations for insurance and retirement schemes are woven, and in the busy world the life assurance companies depend on them for their own livelihood. With an ageing population, and birth rates which—apart from a recent post war increase—have declined steadily over the last seventy years, it becomes of vital importance to know to what extent we are replacing ourselves as a people, it is for this reason that questions are included to discover women's age at marriage, and the number of children that each married woman has had during her lifetime.

In the sphere of medicine almost all the information derived from the Census is valuable: the returns form a well stocked laboratory of social medicine and public health. The rates that are handled in everyday estimates of health and social welfare, such as the birth and death rates, and many of the sensitive indices of social progress or failure, are referred back ultimately to the number of the people. The prevalence of certain diseases owes its discovery to an accurate knowledge of age and sex distribution, and epidemiology in all its length and breadth has the Census as its point of departure. Our knowledge of the principal hazards of industry is intimately related to the information that the Census provides about the number of persons in each occupation, and their age and sex distribution. The registration of deaths and the increasing quantity of facts we receive about injury and sickness join with the Census returns in giving us a clear picture of industrial health and sickness.

The information given for each citizen about his occupation is also used by the Registrars General to break down the population and its mortality experience into social classes, the contrasted experience of which has been helpful in suggesting different types of health hazard associated with varying social environments, and also as a challenge to complacency, holding before us the need to attain for the nation as a whole the standards of experience of the most fortunate. The particulars about occupation and social class depend for their usefulness on a sufficiently detailed description being given of the occupation of each employed person, to get this necessary detail not only must the occupation be described as fully as possible but also the trade in which the work is done, and the name and address of the employer have to be supplied. The Census will likewise give us much new knowledge of housing conditions. The return for Great Britain not only includes the more formal question about the number of living rooms per person, we are also to learn whether the householder has exclusive use of, or has to share, piped water supply, cooking stove, kitchen sink, water-closet, and bath. In the processing of previous censuses a disadvantage has been the long period that had to elapse before the full details could be published for general interest and trade and scientific research. A welcome innovation on this occasion will be the early publication of as much information as possible based on facts derived from a 1% sample of the whole Census population.

The householder scratching his head as he fills in his Census form on Sunday, April 8, may find the task less congenial than his normal sabbath routine, but he may comfort himself with the reflection that our Registrars-General are much more forbearing in their demands than their opposite numbers in most other countries. Relative to the mighty task it must perform, the schedule of questions is a masterpiece of brevity and simplicity, and to a generation trained on football pools the completing of this form should surely be child's play. Past generations have feared to learn unpleasant truths about themselves revealed by census: in a parliamentary debate in 1753 one legislator suggested that a census "may act as the most effective instrument of rapacity ever used against an injured people." With a century and a half behind us of decennial census taking we now know that the dangers are imaginary and the benefits immense. Nevertheless the Registrars General go out of their way to give reassurance against abuse of privilege and to emphasise that the Census "has no connection whatever with assessing individuals for taxation, with pursuing them for insurance contributions, or with compelling them to perform any other social or national obligation." The personal details derived

It is richly illustrated with line drawings (there are almost five hundred) and it has been attractively printed Some sections will probably need rather regular revision, but this is one of the penalties of writing a book which is thoroughly up to date

Handbook of Child Health

AUSTIN FURNISS, L R C P E , L D S , D P H , *chief assistant* school medical officer, West Ham London Sylviro Publications 1950 Pp 280 25*s*

THIS small but solid book is intended in the first place for the student taking a diploma in child health it will certainly be of more use to the examinee than to the pædiatrician or hygienist A wide field is covered, including the physiology of diet and nutrition, the administrative and other aspects of special schools, and the clinical features and treatment of some of the commoner and some of the rarer diseases of childhood Inevitably much of this is handled in only a superficial way, and the book is not a work of reference At its best this is a general survey of the work done in the school health service it is packed full of facts but is heavy reading

Problems in Cerebellar Physiology

G MORUZZI, M D , professor of physiology, University of Pisa, Italy Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 Pp 124 23*s* 6*d*

THIS monograph, based on four lectures given in the Northwestern University three years ago, discusses what is known of the functions of the anterior lobe of the cerebellum, also called the palæocerebellum, which includes the vermis Stimulating this part of the cerebellar mechanisms has important effects on muscle tone, and these are described Professor Moruzzi thus considers the manner in which the cerebellum affects the motor results of activity in the cerebral cortex and spinal cord and examines the intervening structures which might be involved The part played by the " old cerebellum " in modifying tone and movement is related to the activity of the brain stem reticular substance with which it is intimately connected Study of these integrating mechanisms in the central nervous system is now revolutionising our conception of the basis of purposive behaviour within the cerebrum This clear little monograph offers easy access to an aspect of this subject which might well escape the notice of those interested in behaviour in a more general way

Cytologic Diagnosis of Lung Cancer

SEYMOUR M FARBER, M D , MILTON ROSENTHAL, M D , EDWIN F ALSTON, M D , MORTIMER A BENIOFF, M D ALLEN K MCGRATH, Jr , M D , University of California Medical Service and Department of Pathology, San Francisco Hospital, and the San Francisco Department of Public Health Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 Pp 79 45*s*

THE growing importance of early diagnosis of carcinoma of the bronchus, now that thoracic surgery has made such strides in the operative treatment of this condition, has stimulated interest in the laboratory diagnosis, by means of the Papanicolaou technique, of malignant cells in the sputum In this country Dudgeon and his colleagues devised a wet-film technique for this purpose which has since been superseded by various modifications The volume from San Francisco is based upon the study of 1526 cases of non-neoplastic as well as neoplastic diseases of the respiratory tract A full account is given of the different types of normal and abnormal cell that may be encountered in films from sputum and bronchial washings These are illustrated by 60 excellent colour photomicrographs An impressive percentage of positive diagnoses, later confirmed either by biopsy or necropsy, was obtained by these workers, who made their examinations without clinical information to bias their judgment But they properly emphasise the caution required in using this type of diagnostic aid , in particular the novice needs long training to recognise the bizarre forms of non-malignant cells that may appear in films

The Anatomy of Man and Other Animals, or Brothers Under the Skin (London Watts 1951 Pp 158 18*s*)—This work by *Dr D Stark Murray and Miss Grace M Jeffree* is a clear elementary description of the probable course of evolution of the animal world, laying special emphasis on " the great variety of uses and of external form with which nature has endowed a fundamental structure which comes clearly from one source," and " the many ways in which nature has sought to do the same job with different types of organ.' Within this limited field the authors have successfully performed what they set out to do The book would have been excellent for senior school children if it had been couched in simpler language It is worthy of a better index

Clinical Orthoptic Procedure (London Henry Kimpton 1950 Pp 393 56*s*)—Mr William Smith is an orthoptist in the Massachusetts School of Optometry, and his book illustrates, in our opinion, the harm *that is done when practitioners* without a medical training are allowed to treat the general public for such conditions as squint He refracts children of 16 months without a cycloplegic and prescribes glasses for them on this refraction he gives case histories without any follow up to show what happened to the patient, and nowhere does he clearly enunciate *the axiom that orthoptic* treatment for heterophoria is indicated only where there are symptoms due to the imbalance

Medical Dictionary (Berne Huber *1951* Sw fr [illegible])—This enterprising new work, edited by Dr E Veillon with the help of a number of colleagues, is really three dictionaries in one cover , for German English French, French German English, and English French German translations are set out synoptically in separate sections, each of close on 500 pages Dr Veillon does not pretend that the dictionary is complete, but it is reasonably full and special heed is given to anatomical terms British readers may be a little daunted to find the Old World following the New in the spelling of such words as " anemia, ' color," and "edema "

An Introduction to the Theory of Statistics (14th ed London Charles Griffin 1950 Pp 701 34*s*)—*The title* of this classical text by G Udny Yule, F.R.S., and M G Kendall D SC , does less than justice to its most recent revision and expansion , for Professor Kendall has imparted a fresh vitality to the work Of particular importance in medical work is the expansion of the treatment of small samples and the emphasis on both the theory and the practice of sampling inquiries Although primarily intended for use *in the study of economics, the new chapters on index* numbers and the elementary theory of time series have their potential value to research workers in social medicine and epidemiology

No profound mathematical knowledge is needed to assimilate the contents of this book , it is enough to have a nodding acquaintance with algebra up to the binomial theorem, and a little analytical geometry No serious student of the quantitative aspects of any branch of medical research should be dissuaded by the occasional burst of symbolism from reading it

Microanalysis in Medical Biochemistry (2nd ed London J & A Churchill 1951 Pp 222 14*s*)—In this new edition of Prof E J King's book, the first chapter, on normal values has been considerably altered A new table of levels of the major constituents of blood, based on a statistical survey of some 80 normal *subjects*, replaces the *former* table which quoted generally accepted values Some of the figures listed are so controversial that readers will want to know whether an adequate *foundation* has *been provided* for such drastic revision of limits , and though Professor King indicates that the table is intended *only for* use with *the methods* described in the text, its publication can only be justified if it stimulates more widespread investigations on similar lines The general plan of the book remains very much the same, but some *methods* have been revised, and the inclusion of a further selection of biochemical procedures has increased the size Most workers in medical biochemistry have their own *tried* and trusted methods which they are loth to desert, and for this reason any criticism of the methods selected here would be *out of place* Professor King is always ready to adopt *or adapt* the latest refinements in technique as they are published and this quality of progress is one of the most attractive features *of a book* which has become essential *to the laboratory* bookshelf

THE LANCET

LONDON SATURDAY, MARCH 24, 1951

On April 8

THE Census of 1951 is everybody's story, and nobody's. It belongs to everyone, because each of us contributes a brick to its immense structure; and to nobody, because not one of those bricks carries a name and address. The Census is one of the few human institutions that bring benefit to every citizen and harm to none. In its modern shape the information that it reveals tells us not only where we stand, in number and proportion, but also in what direction we are moving. At the present time our nation urgently needs this information, for the last numbering of the people took place as long ago as 1931. The intervention of the blitz ten years ago tore a great hole in our knowledge about population, life, and death, and the gap could only be loosely plugged by more or less inspired guesswork.

The broad general uses of a census are obvious enough, but it is just as well that we should count the blessings we derive from it. The national population returns, and their breakdown into the smallest units of local government, form the only accurate basis for the daily business of living. Some of the figures could be obtained by other means, but the Census is the most economical way of doing the job. Its records are props to trade at every level, and they are indispensable for the administrative activities of local authorities. The shifting pattern of modern industry and the disrupting forces of war have brought important regional changes in the distribution of our population; how great the changes are we can only estimate today, and we need the Census to give exact information to help in the convenient siting of industry and in town and country planning. Again, the vital statistics which are compiled from the Census returns—the tale of birth, death, marriage, and fertility rates—are the stuff out of which national calculations for insurance and retirement schemes are woven; and in the busy world the life assurance companies depend on them for their own livelihood. With an ageing population, and birth-rates which—apart from a recent post-war increase—have declined steadily over the last seventy years, it becomes of vital importance to know to what extent we are replacing ourselves as a people; it is for this reason that questions are included to discover women's age at marriage, and the number of children that each married woman has had during her lifetime.

In the sphere of medicine almost all the information derived from the Census is valuable: the returns form a well stocked laboratory of social medicine and public health. The rates that are handled in everyday estimates of health and social welfare, such as the birth and death rates, and many of the sensitive indices of social progress or failure, are referred back ultimately to the number of the people. The prevalence of certain diseases owes its discovery to an accurate knowledge of age and sex distribution, and epidemiology in all its length and breadth has the Census as its point of departure. Our knowledge of the principal hazards of industry is intimately related to the information that the Census provides about the number of persons in each occupation, and their age and sex distribution. The registration of deaths and the increasing quantity of facts we receive about injury and sickness join with the Census returns in giving us a clear picture of industrial health and sickness.

The information given for each citizen about his occupation is also used by the Registrars General to break down the population and its mortality experience into social classes, the contrasted experience of which has been helpful in suggesting different types of health hazard associated with varying social environments, and also as a challenge to complacency, holding before us the need to attain for the nation as a whole the standards of experience of the most fortunate. The particulars about occupation and social class depend for their usefulness on a sufficiently detailed description being given of the occupation of each employed person; to get this necessary detail not only must the occupation be described as fully as possible but also the trade in which the work is done, and the name and address of the employer have to be supplied. The Census will likewise give us much new knowledge of housing conditions. The return for Great Britain not only includes the more formal question about the number of living rooms per person; we are also to learn whether the householder has exclusive use of, or has to share, piped water-supply, cooking stove, kitchen sink, water closet, and bath. In the processing of previous censuses a disadvantage has been the long period that had to elapse before the full details could be published for general interest and trade and scientific research. A welcome innovation on this occasion will be the early publication of as much information as possible based on facts derived from a 1% sample of the whole Census population.

The householder scratching his head as he fills in his Census form on Sunday, April 8, may find the task less congenial than his normal sabbath routine; but he may comfort himself with the reflection that our Registrars General are much more forbearing in their demands than their opposite numbers in most other countries. Relative to the mighty task it must perform, the schedule of questions is a masterpiece of brevity and simplicity, and to a generation trained on football pools the completing of this form should surely be child's play. Past generations have feared to learn unpleasant truths about themselves revealed by census: in a parliamentary debate in 1753 one legislator suggested that a census "may act as the most effective instrument of rapacity ever used against an injured people." With a century and a half behind us of decennial census-taking we now know that the dangers are imaginary and the benefits immense. Nevertheless the Registrars General go out of their way to give reassurance against abuse of privilege and to emphasise that the Census "has no connection whatever with assessing individuals for taxation, with pursuing them for insurance contributions, or with compelling them to perform any other social or national obligation. The personal details derived

It is richly illustrated with line drawings (there are almost five hundred) and it has been attractively printed Some sections will probably need rather regular revision, but this is one of the penalties of writing a book which is thoroughly up to date

Handbook of Child Health

AUSTIN FURNISS, L R C P E , L D S , D P H , chief assistant school medical officer, West Ham London Sylviro Publications 1950 Pp 280 25s

THIS small but solid book is intended in the first place for the student taking a diploma in child health it will certainly be of more use to the examinee than to the pædiatrician or hygienist A wide field is covered, including the physiology of diet and nutrition, the administrative and other aspects of special schools, and the clinical features and treatment of some of the commoner and some of the rarer diseases of childhood Inevitably much of this is handled in only a superficial way, and the book is not a work of reference At its best this is a general survey of the work done in the school health service it is packed full of facts but is heavy reading

Problems in Cerebellar Physiology

G MORUZZI, M D , professor of physiology, University of Pisa, Italy Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 Pp 124 23s 6d

THIS monograph, based on four lectures given in the Northwestern University three years ago, discusses what is known of the functions of the anterior lobe of the cerebellum, also called the palæocerebellum, which includes the vermis Stimulating this part of the cerebellar mechanisms has important effects on muscle tone, and these are described Professor Moruzzi thus considers the manner in which the cerebellum affects the motor results of activity in the cerebral cortex and spinal cord and examines the intervening structures which might be involved The part played by the " old cerebellum " in modifying tone and movement is related to the activity of the brain-stem reticular substance with which it is intimately connected Study of these integrating mechanisms in the central nervous system is now revolutionising our conception of the basis of purposive behaviour within the cerebrum This clear little monograph offers easy access to an aspect of this subject which might well escape the notice of those interested in behaviour in a more general way

Cytologic Diagnosis of Lung Cancer

SEYMOUR M FARBER, M D , MILTON ROSENTHAL, M D , EDWIN F ALSTON M D , MORTIMER A BENIOFF, M D , ALLEN K McGRATH, Jr , M D , University of California Medical Service and Department of Pathology San Francisco Hospital, and the San Francisco Department of Public Health Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1950 Pp 70 45s

THE growing importance of early diagnosis of carcinoma of the bronchus, now that thoracic surgery has made such strides in the operative treatment of this condition, has stimulated interest in the laboratory diagnosis, by means of the Papanicolaou technique, of malignant cells in the sputum In this country Dudgeon and his colleagues devised a wet film technique for this purpose which has since been superseded by various modifications The volume from San Francisco is based upon the study of 1526 cases of non-neoplastic as well as neoplastic diseases of the respiratory tract A full account is given of the different types of normal and abnormal cell that may be encountered in films from sputum and bronchial washings These are illustrated by 60 excellent colour photomicrographs An impressive percentage of positive diagnoses, later confirmed either by biopsy or necropsy, was obtained by these workers, who made their examinations without clinical information to bias their judgment But they properly emphasise the caution required in using this type of diagnostic aid , in particular the novice needs long training to recognise the bizarre forms of non-malignant cells that may appear in films

The Anatomy of Man and Other Animals, or Brothers Under the Skin (London Watts 1951 Pp 158 18s)—This work by Dr D Stark Murray and Miss Grace M Jeffree is a clear elementary description of the probable course of evolution of the animal world, laying special emphasis on " the great variety of uses and of external form with which nature has endowed a fundamental structure which comes clearly from one source," and " the many ways in which nature has sought to do the same job with different types of organ." Within this limited field the authors have successfully performed what they set out to do The book would have been excellent for senior school children if it had been couched in simpler language It is worthy of a better index

Clinical Orthoptic Procedure (London Henry Kimpton 1950 Pp 393 56s)—Mr William Smith is an orthoptist in the Massachusetts School of Optometry, and his book illustrates, in our opinion, the harm that is done when practitioners without a medical training are allowed to treat the general public for such conditions as squint He refracts children of 16 months without a cycloplegic and prescribes glasses for them on this refraction , he gives case histories without any follow up to show what happened to the patient and nowhere does he clearly enunciate the axiom that orthoptic treatment for heterophoria is indicated only where there are symptoms due to the imbalance

Medical Dictionary (Berne Huber 1951 Sw fr 65)—This enterprising new work, edited by Dr E Veillon with the help of a number of colleagues, is really three dictionaries in one cover , for German English French, French German English, and English French German translations are set out synoptically in separate sections, each of close on 500 pages Dr Veillon does not pretend that the dictionary is complete, but it is reasonably full and special heed is given to anatomical terms British readers may be a little daunted to find the Old World following the New in the spelling of such words as " anemia," color," and "edema "

An Introduction to the Theory of Statistics (14th ed London Charles Griffin 1950 Pp 701 34s)—The title of this classical text by G Udny Yule, F.R.S , and M G Kendall, D SC , does less than justice to its most recent revision and expansion , for Professor Kendall has imparted a fresh vitality to the work Of particular importance in medical work is the expansion of the treatment of small samples and the emphasis on both the theory and the practice of sampling inquiries Although primarily intended for use in the study of economics, the new chapters on index numbers and the elementary theory of time series have their potential value to research workers in social medicine and epidemiology

No profound mathematical knowledge is needed to assimilate the contents of this book it is enough to have a nodding acquaintance with algebra up to the binomial theorem, and a little analytical geometry No serious student of the quantitative aspects of any branch of medical research should be dissuaded by the occasional burst of symbolism from reading it

Microanalysis in Medical Biochemistry (2nd ed London J & A Churchill 1951 Pp 222 14s)—In this new edition of Prof E J King's book, the first chapter, on normal values has been considerably altered A new table of levels of the major constituents of blood, based on a statistical survey of some 80 normal subjects, replaces the former table which quoted generally accepted values Some of the figures listed are so controversial that readers will want to know whether an adequate foundation has been provided for such drastic revision of limits , and though Professor King indicates that the table is intended *only* for use with the methods described in the text, its publication can only be justified if it stimulates more widespread investigations on similar lines The general plan of the book remains very much the same, but some methods have been revised, and the inclusion of a further selection of biochemical procedures has increased the size Most workers in medical biochemistry have their own tried and trusted methods which they are loth to desert, and for this reason any criticism of the methods selected here would be out of place Professor King is always ready to adopt or adapt the latest refinements in technique as they are published and this quality of progress is one of the most attractive features of a book which has become essential to the laboratory bookshelf

Anticoagulants in Cardiac Infarction

OUR cardiologists have been slow to accept the claims made for the anticoagulants in cardiac infarction, and even today, though some are enthusiastic believers, others remain unconvinced It is only reasonable to demand strong evidence, for anticoagulant therapy involves a considerable expenditure of time, trouble, and money, the technique must be scrupulous, and the coagulability of the blood must be maintained at exactly the right level for several weeks Then there are the hazards inherent in any interference with blood clotting—bleeding into the tissues generally, into the wall of the atheromatous coronary artery, and into the cardiac infarct itself with perhaps an increased risk of ventricular rupture However, aggravation of the cardiac lesion has not been observed in animal experiments, and, judging by the clinical reports, rupture of the ventricle has not become any more common in patients treated with anticoagulants The proportion of cases in which a hæmorrhage into the coronary wall leads directly or indirectly to obstruction of the lumen has been variously assessed at 5–65%, and there can be no doubt that cardiac infarction very often occurs without any recent thrombosis Thus among the 114 cases of gross infarction analysed by **YATER** and his colleagues[1] there were 35 without coronary thrombosis, and less than half of the 336 other fatal cases of coronary disease showed coronary thrombosis These considerations, however, are of no practical importance if it can be shown clinically, in a large series of properly controlled cases, that anticoagulants have a beneficial effect in major attacks of cardiac ischæmia—that is, in the cases clinically termed coronary thrombosis

In Denmark, **HOLTEN**[2] has collected the results of a two-year trial at 21 clinics in which 174 patients were treated with anticoagulants and 256 without It was intended to allot patients to the treated and control groups on alternate days, and, though this rule was not strictly adhered to, the variations have been shown not to affect the results There was a substantial difference in the mortality of the two groups (presumably over a period of a few weeks) After excluding 52 patients who died within 24 hours of admission, the mortality of the treated patients was 22 5% and of the untreated 36% When the patients are divided into age groups the only groups with enough cases to be significant are 50–59, 60–69, and 70–79 in which there were 149 treated cases with mortality 23%, and 229 controls with mortality 37% But at ages 50–59 and 70–79 the mortality is only 4–5% lower in the anticoagulant-treated cases than in the controls Thus in the treated group as a whole the evidence in favour of anticoagulant therapy largely depends on the experience at age 60–69 (mortality of treated cases 17% and of controls 43%)—a peculiar result which requires explanation In the large American series reported by **WRIGHT** and colleagues[3] the benefit of anticoagulants appeared to be greatest in patients aged 70 and over, and the figures given by **TULLOCH** and **GILCHRIST**[4] in England are similar

When we turn to the causes of death, thrombo-embolism was 3½ times as frequent in **HOLTEN**'s controls (14%) as in his treated patients, though it is impossible to assess the significance of this complication in the fatal outcome Apart from shock in the earliest stages, the deaths presumably were either due to congestive failure or occurred suddenly from ventricular fibrillation or asystole, which is the general experience If anticoagulants are to prevent these disasters they must do so largely by preventing clotting in the coronary lumen, though embolism, particularly in the lung, may sometimes be a contributory cause of death **HOLTEN** and **TULLOCH** and **GILCHRIST** seem to agree with this view of their action, but **WRIGHT** et al regard the main rôle of anticoagulants as the prevention of thrombo embolism Such theoretical considerations cannot affect the statistics, which, if they cannot be taken at their face value, certainly cannot be disregarded The time will soon come, it is to be hoped, when we shall know whether the routine use of anticoagulants in coronary thrombosis is worth while or not

IMMERSION IN COLD WATER

Two world wars have taught us something of the chances for seafarers and others who are immersed in northern waters Critchley, in his Bradshaw lecture,[5] remarked that of 10 men from a torpedoed vessel who were immersed in water at −1 7°C, only 1 survived half an hour, but a corpulent man of 29, clad in indoor clothes and duffel coat, remained swimming in the Barents Sea in July at a temperature of −1 5°C for nine to fourteen hours Molnar[6] describes a group of 23 people who all survived four hours in a sea at 8°C, even though experiments in baths suggested that this should have lowered the rectal temperature to 24°C, and that few would survive in water near freezing point for more than half an hour and none for more than an hour and a half

This seeming anomaly is explained by Glaser[7] from observations on a man swimming in water at 20°C with a Douglas bag on his back Glaser remarks that if this subject had been swimming in colder water his heat production would have been similar, for Spealman[8] has made it clear that, in the absence of shivering, heat production during immersion does not depend on water temperature, and, says Glaser

> ' a man who is swimming hard should produce about as much heat as he loses in water near freezing point and he should not die of cold as long as he is able to swim Stiffness of the muscles may eventually interfere with efficient swimming, but muscles which are being exercised hard may remain warm enough to prevent them from becoming stiff Men in baths may shiver but only after they have lost much heat, and they cannot produce enough heat by this means alone to balance their losses in very cold water

Glaser concludes "Fit men therefore, who are in danger of immersion in cold water, might be advised to swim or struggle as hard as they can for as long as they can If they try to preserve their strength by clinging to wreckage or floating on their lifebelts, they will die from cold Perhaps more lives would have been saved in the past if this had been understood " from the returns are treated by the Registrars General and their staffs and by all engaged in taking the Census in complete and absolute confidence and used for statistical purposes only—never in any circumstances to the detriment of the individual concerned "[1] The integrity of the Census administration can be taken for granted It is now up to all citizens to do their duty, for self knowledge is one of the badges of a free people

The Pituitary and the Blood

In man, the injection of a small dose of pituitary adrenocorticotropic hormone (A C T H) produces a fall in the eosinophil granulocytes of the peripheral blood which is maximal after about 4 hours In mice and rats, however, the most characteristic effect of A C T H is a reduction in the circulating lymphocytes , and it occurred to G W Harris and his physiologist colleagues at Cambridge[2] that this temporary lymphopenia could be used as an indicator of adrenocorticotropic hormone activity and as a means of studying the pathways in the central nervous system through which pituitary stimulation occurs They worked with rabbits, so they had first to confirm that A C T H does cause lymphopenia in these animals, and then to find out whether emotional stress in the rabbit has a similar effect on the lymphocytes, as it has in mice and rats It was soon established that immobilisation of a rabbit in clamps for 3 hours reduced its circulating lymphocytes by about 30%, whereas its granulocytes increased They were able to show that rabbits which have had their hypophysis removed no longer develop lymphopenia after stress , but if the animal is injected intravenously with crude anterior pituitary extract beforehand emotional stress will again produce lymphopenia The conclusions drawn from these findings are that emotional lymphopenia is mediated by stimulation of the pituitary, and that the adrenocorticotropic hormone secreted is the actual lymphopenic agent The possibility of direct nervous stimulation of the adrenal was excluded by denervating the adrenal glands and showing that the reaction was unaffected , the adrenal medulla was unlikely to be involved because injections of adrenaline normally have no effect on the blood lymphocytes

Next, De Groot and Harris[3] tackled the nerve pathways It seemed that the lymphopenic reaction could again be used, for Mikkelsen and Hutchens[4] had found in man that electric shock therapy is followed by a lymphopenia 3 hours later The Cambridge workers adopted an ingenious indirect electrical method of stimulating the relevant parts of the central nervous system in unanæsthetised but quiescent rabbits Local stimulation of the posterior part of the tuber cinereum or of the mamillary bodies, in the floor of the third ventricle produced a typical lymphopenic response, which could be abolished by cutting transversely through these areas or the zona tuberalis of the pituitary body itself Thus there is good reason for believing that the secretion of the anterior pituitary which causes lymphopenia presumably A C T H , is controlled by the hypothalamus Stimuli from the hypothalamus do not reach the pituitary via the cervical sympathetic nerves, since cutting them does not affect the lymphopenic response Green and Harris[5] had previously suggested that the hypothalamus influences pituitary secretion by two steps nerve fibres pass from the hypothalamus to the median eminence, where a humoral transmitter is liberated into the portal vessels of the pituitary gland and so carried to the anterior lobe cells The experimental findings are said to support this view

Lymphopenia is uncommon in man It occur after over exposure to radium, and the textbooks vaguely associate it with severe illnesses and bad prognoses Shillitoe[6] has analysed the 647 routine differential white cell counts done in his laboratory during a year, and has found 87 lymphocyte counts of 1000 per c mm or less , but these counts were not constantly associated with any particular clinical state Heinle and colleagues[7] have been trying to find out where the lymphocytes go when they disappear from the peripheral blood The original hypothesis of Dougherty and White was that they lost their cytoplasm and were then picked up by the lymphoid tissues, where they regenerated When Heinle et al transfused rats with lymphocytes labelled with radioactive phosphorus (P^{32}), after a quarter of an hour most of the labelled lymphocytes had left the circulation and accumulated in the lungs and to less extent in the spleen They repeated the experiment with rats which had been injected with A C T H or 'Cortisone' 4 hours previously and obtained the same results It does not necessarily follow that when patients develop a lymphopenia their lymphocytes congregate in the lungs or spleen It is unfortunate for the hæmatologist that rodents are the easiest laboratory animals to maintain, because the reactions of their blood and blood forming tissues to various drugs and other stimuli are sometimes strikingly different from those in man The most notable difference of this kind has been in the effects of folic acid deficiency In the rat the predominant change is a diminution in the granulocyte producing tissues, erythropoiesis being little affected , in man, on the other hand, lack of folic acid seems to be accompanied by megaloblastic erythropoiesis, of which no hint could be gleaned from the rat experiments Such differences have also made it difficult to interpret the experimental work on the relation between the pituitary gland and blood cells For instance, Piliero et al[8] have shown in rats that adrenalectomy increases granulopoiesis and decreases erythropoiesis in the bone marrow, besides causing abnormalities of maturation , and that cortisone restores the picture to normal But such changes have not been observed in, for example, patients with Addison s disease For the present it seems wise not to draw clinical conclusions about the influence of the pituitary gland on blood cells from the theories based on observations in rodents

What of resuscitation ? Light cradles, heated sleeping bags, and friction are less effective than rapid rewarming by direct immersion in water at temperatures of up to 50°C, maintained until peripheral vascular spasm is dispelled Characteristically, the subject gives a sharp outcry, and then the laboured respiration and muscular rigidity disappear With brisk rubbing and wrapping in warm blankets the temperature is restored to normal in about three hours

MEDICAL SECRECY AND ABORTION

In our leading article of Feb 24 we drew attention to the legal safeguards which foreign systems, in contrast to the common law, have established to protect confidential communications between doctors and their patients Happenings in two towns of Western Germany at the end of February show that even these measures to prevent breaches of medical secrecy may not go far enough They also illustrate how jealously the public on the Continent resist any attempt to whittle down, by official action, what they have come to regard as a fundamental right of the individual

Under a statute of 1935, re enacted in 1946–47, practitioners in Western Germany have to notify to the public health authorities, *for the purpose of registration and* statistics, any abortions among patients under their care There seemed to be no danger in such action until it occurred to the public prosecutor of the town of Weinheim (Baden) that the information thus assembled might be useful for tracking down professional abortionists, whose activities have lately increased The prosecutor asked the local health authority to give him a copy of the relevant list of women treated for hæmorrhages, &c , during the past six months, and in due course the police were told to summon and interrogate the women named in the list Perhaps in an excess of zeal, the local chief of police ordered a raid during which some 200 women and girls from the town and neighbourhood were taken in vans to the police station and kept there several hours for questioning and further investigation, on no other ground than that they had been treated within the last six months for miscarriage

How far this measure succeeded in its purpose is not yet known , for this aspect of the affair has been submerged by a wave of protests from the doctors of the district and from the public Concern has been aroused all over Germany, particularly since it became known that a similar attempt to get evidence of criminal abortions from official returns of miscarriages had been made by the police at Garmisch (Bavaria) In its indignation over the high handed action of the police, the German press has not lost sight of the wider principles involved, and much of the outcry has been directed against the public health officials for their " gross breach of medical secrecy " in passing the list of names to the public prosecutor The local medical organisation has advised its members to suspend all notifications of abortion until the legality of the recent police action has been investigated, and an information has been laid against the health officials concerned for breach of medical and official secrecy This step has been endorsed by the medical chamber of the Land, which demands new legislation to provide legal safeguards against such breaches of medical secrecy, if the present rules should be found insufficient After this sharp reaction of public and medical opinion in Western Germany such attempts to circumvent medical secrecy are not likely to be repeated, the more so since German law clearly says that in no circumstances can such a breach be ordered even for the purpose of pursuing punishable conduct

In this country the duties of medical practitioners in relation to cases of criminal abortion which have come to their knowledge in the course of treatment were the subject of a resolution passed by the Royal College of Physicians in 1916 After emphasising " the moral obligation to respect the confidence of the patient," this advised the practitioner to urge his patient to make a statement to the police , but if such a statement is refused, he is under no legal obligation to take further action and should continue to treat the patient It is less easy to give any definite answer to the further question which the incidents in Germany may raise here—namely, whether the records of patients and treatment which have to be forwarded to the local executive council under the National Health Service regulations, and the written clinical information which may be requested by the medical officer of health, are, in theory or even in practice, open to similar misuse There is, however, some authority for suggesting that, if the Government department concerned were to object to the revelation of such documents to the police, the courts would uphold the objection on the ground that the papers are protected as State documents

CARE OF THE TEETH

Though its causes lie chiefly in diet, much dental caries could be prevented or checked if people could be induced to keep their mouths clean and see a dentist regularly Recognising that, for many years at least, *most dental surgeons will be occupied mainly in dental* repairs, Mr G H Leatherman [1] bases his scheme of preventive care on the employment of women dental ancillaries, or " hygienists," who would undertake scaling and polishing, and would help to instruct patients or parents in the elements of oral hygiene and home treatment Whereas adults, and possibly adolescents, should be seen first by the dental surgeon, who would refer the patient to the hygienist for any minor treatment required, Mr Leatherman thinks that for the very young the sequence should be reversed, because it is psychologically better for the child to be introduced to dental care by a woman He recommends that polishing of the teeth, mouth charting, and the taking of " wing bite " radiographs should be done by the hygienist before the child goes to the dental surgeon for detailed examination and treatment This proposal, however, when he made it before the British Dental Association at Birmingham was strongly criticised,[2] mainly on the ground that diagnosis should precede treatment and that scaling alters the diagnostic picture Mr A F Stammers did not regard scaling as by any means minor dental work it was, he said, the most important thing a dental surgeon could do for his patient Mr E Davies-Thomas, at the Children's Hospital, Birmingham, had made a rule that nobody should talk to the child except himself, and in this way he established a personal understanding

In the care of the teeth at home, Mr Leatherman believes that the basic need from childhood is to prevent gingivitis, and, where gingivitis and its sequelæ have developed, to see that the causes are removed and the supporting structures rendered healthy The patient should be made to understand that the supporting structures of the teeth require as much attention as the surfaces of the teeth themselves, and to this end the term toothbrush should be changed to mouthbrush He favours the use of a mouthwash of full strength hydrogen peroxide (10 volumes), or 'Milton' (1 part to 4 parts water), or sodium chloride and sodium bicarbonate ($^1/_2$ teaspoonful of each in half a glass of warm water) The teeth and mouth are brushed first thing in the morning and last thing at night with salt powder, or a powder of urea and ammonium , though what really matters is not what is on the brush but how and when the brush is used The brush of choice, according to Mr Leatherman, is one of natural bristle, of medium consistence, 6–8 rows long, the bristles being all of the same length , and more than one brush is necessary, for each should be allowed to dry for at least 24 hours after use. He would have us all clean our dental spaces with wooden sticks or dental floss, and some people should massage the interdental epithelium with a wooden stick. At each mouth cleaning the gums are massaged with the fingers, and the session ends with a mouthwash.

BLEEDING AT OPERATIONS

PERSISTENT oozing of blood during an operation may cause nothing worse than irritation and delay—in itself the loss of blood is not often serious nowadays, when it can easily be made up by transfusion—but it may obscure the surgeon's view and lead to damage of important structures, or by forming a hæmatoma it may delay healing and encourage infection. Surgeons and anæsthetists are inclined to blame each other for such oozing, and almost every anæsthetic agent has at some stage of its career been accused of increasing the bleeding tendency; so the subject has been keenly studied. It seems to be generally agreed that cyclopropane encourages bleeding, though whether this is a direct effect of the gas or a result of the absorption method of administration or of the presence of excess of oxygen is uncertain. Ether is also suspect, because, except in very deep anæsthesia, it stimulates cardiac and respiratory activity and dilates the peripheral vessels. Apart from drug action, bleeding can be aggravated by respiratory obstruction sufficient to raise the venous pressure, and also by breathing excessive amounts of carbon dioxide, whether this comes direct from the cylinder or from a faulty absorber or mismanaged anæsthetic apparatus. Then the surgeon himself may be responsible—for example, he can obstruct the venous return by leaning on the patient, or with his bandages, or, in tonsillectomy, with the tourniquet-like straps of his gag jack.

Two methods of anæsthesia have long been noted for a striking absence of bleeding—chloroform and spinal anæsthesia. Their common feature is that they usually cause a considerable fall in blood-pressure. This effect has lately been developed in several directions to reduce bleeding, the two main techniques being (1) high spinal anæsthesia[1] extensive enough to cut off all the sympathetic outflow, and (2) the injection of drugs of the methonium group which act selectively on the sympathetic ganglia.[2] Both of these will produce a profound fall in blood-pressure and ensure a bloodless field for the surgeon. In brain surgery, where bleeding is particularly apt to be troublesome, there is an additional factor—intracranial tension, on which ease of access and the avoidance of surgical trauma largely depend. Intracranial tension is in turn dependent on arterial blood-pressure, so by reducing the B.P. it is possible both to control bleeding and keep the intracranial tension low. At Edinburgh Royal Infirmary Bilsland[3] has attained this end with the technique introduced by Gardner[4] in the U.S.A. as "controlled induced hypotension by arteriotomy," an adaptation of the method used experimentally for inducing shock in animals. In this blood is rapidly withdrawn through a cannula in the radial artery until the desired reduction of B.P. is attained. The blood is run into a reservoir, from which, usually towards the end of the operation, it is returned to the patient by the same route, simply by raising the pressure in the reservoir to above the patient's systolic B.P. In 63 craniotomy cases a B.P. of under 100 mm. Hg has been maintained for up to 6 hours by withdrawing 300–2600 ml. of blood, and only one death could be put down to the hypotension.

Last year Dr. Enderby[2] published in these columns his preliminary results with "controlled hypotension," attained with penta- or hexa-methonium iodide or tetraethylammonium chloride, supplemented by a careful use of posture. The technique, though based on that described by Griffiths and Gillies,[5] was exploratory; nevertheless, Enderby obtained a satisfactory reduction of bleeding in about half of his 85 cases, and the ill-effects were nil. In this issue (p. 663) he and Dr. Pelmore report subsequent experience. Using hexamethonium only, with posture when possible, the proportion of successes has risen to 85% in 250 cases. In fenestration, where the slightest bleeding at the wrong place reduces the chances of success, Dr. Hughes (p. 666) has lowered the systolic B.P. to 75–80 mm. Hg with pentamethonium and posture (plus pentothal and pethidine, "the four P's") and produced a completely bloodless field with no ill effects in 10 cases. But, as several speakers emphasised at the Royal Society of Medicine discussion on March 2, this is not a technique for the inexperienced or inattentive: unless the anæsthetist can keep a constant eye on B.P. and pulse, the behaviour of vessels at the operation site, colour changes, and the state of the peripheral circulation, he had better be content with preventing venous congestion, ensuring a free airway, and the other classical methods of minimising bleeding.

"FAMILY DOCTOR"

THE public appetite for information about medicine is so insatiable as to seem a little morbid, and in fact it is evidence of a deficiency disease. People ingest masses of information, supplied from various sources, in the hope of getting the small amounts of knowledge they need for bodily and mental efficiency. Often this knowledge is of a kind they could get in a few minutes' leisurely conversation with a trusted general practitioner; but for one reason or another they have not got it. In producing a journal that will supplement the efforts of clinicians, educationists, and publicists to meet the large and legitimate demand for sound instruction, the British Medical Association has chosen the title *Family Doctor*, and the editor, Dr. Harvey Flack, aims at making it friendly and dependable, like the good G.P. In a letter introducing the first issue, Dr. Hugh Clegg, editor of the *British Medical Journal*, says that the title "may remind you that the doctor's main concern is to make and keep people well," and he hopes that the new magazine will help everyone to lead a healthy and happy life—"by telling the reader all the medical profession knows about the rules of health for men and women, boys and girls, and for babies." Lord Horder, in a message of encouragement entitled Health is Your Right, speaks of the difficulty caused in this country by medical writers wanting to preserve their anonymity, whereas the newspapers have wanted "not only the 'story' but the signature and, for preference, the photograph also, of the writer." In this demand the newspapers have reflected the opinion of the public, who like to know that the person addressing them is an authority; but the difficulty will be largely overcome if readers can feel that, though an article bears no signature, it comes to them with the imprimatur of over 60,000 members of the B.M.A.[6] The success of the American Medical Association's popular magazine *Hygeia* (now called *Today's Health*) is an encouraging precedent, and we congratulate the *B.M.J.* on the birth of this seventeenth child, which will be the public relations officer for its more academic brothers and sisters.

LORD ADDISON

IN his new office as Lord President of the Council, Lord Addison will find himself on largely familiar ground; for the Privy Council is responsible for the General Medical Council, with which his name is registered, and the Privy Council also has under its ægis the Medical Research Council, of which he has been chairman since 1948. Lord Addison remains leader of the House of Lords.

MEDICAL SECRECY AND ABORTION

IN our leading article of Feb 24 we drew attention to the legal safeguards which foreign systems, in contrast to the common law, have established to protect confidential communications between doctors and their patients Happenings in two towns of Western Germany at the end of February show that even these measures to prevent breaches of medical secrecy may not go far enough They also illustrate how jealously the public on the Continent resist any attempt to whittle down, by official action, what they have come to regard as a fundamental right of the individual

Under a statute of 1935, re enacted in 1946–47, practitioners in Western Germany have to notify to the public health authorities, for the purpose of registration and statistics, any abortions among patients under their care There seemed to be no danger in such action until it occurred to the public prosecutor of the town of Weinheim (Baden) that the information thus assembled might be useful for tracking down professional abortionists, whose activities have lately increased The prosecutor asked the local health authority to give him a copy of the relevant list of women treated for hæmorrhages, &c , during the past six months, and in due course the police were told to summon and interrogate the women named in the list Perhaps in an excess of zeal, the local chief of police ordered a raid during which some 200 women and girls from the town and neighbourhood were taken in vans to the police station and kept there several hours for questioning and further investigation, on no other ground than that they had been treated within the last six months for miscarriage

How far this measure succeeded in its purpose is not yet known , for this aspect of the affair has been submerged by a wave of protests from the doctors of the district and from the public Concern has been aroused all over Germany, particularly since it became known that a similar attempt to get evidence of criminal abortions from official returns of miscarriages had been made by the police at Garmisch (Bavaria) In its indignation over the high handed action of the police, the German press has not lost sight of the wider principles involved, and much of the outcry has been directed against the public health officials for their " gross breach of medical secrecy " in passing the list of names to the public prosecutor The local medical organisation has advised its members to suspend all notifications of abortion until the legality of the recent police action has been investigated, and an information has been laid against the health officials concerned for breach of medical and official secrecy This step has been endorsed by the medical chamber of the Land, which demands new legislation to provide legal safeguards against such breaches of medical secrecy, if the present rules should be found insufficient After this sharp reaction of public and medical opinion in Western Germany such attempts to circumvent medical secrecy are not likely to be repeated, the more so since German law clearly says that in no circumstances can such a breach be ordered even for the purpose of pursuing punishable conduct

In this country the duties of medical practitioners in relation to cases of criminal abortion which have come to their knowledge in the course of treatment were the subject of a resolution passed by the Royal College of Physicians in 1916 After emphasising " the moral obligation to respect the confidence of the patient," this advised the practitioner to urge his patient to make a statement to the police , but if such a statement is refused, he is under no legal obligation to take further action and should continue to treat the patient It is less easy to give any definite answer to the further question which the incidents in Germany may raise here— namely, whether the records of patients,and treatment which have to be forwarded to the local executive council under the National Health Service regulations, and the written clinical information which may be requested by the medical officer of health, are, in theory or even in practice, open to similar misuse There is, however, some authority for suggesting that, if the Government department concerned were to object to the revelation of such documents to the police, the courts would uphold the objection on the ground that the papers are protected as State documents

CARE OF THE TEETH

THOUGH its causes lie chiefly in diet, much dental caries could be prevented or checked if people could be induced to keep their mouths clean and see a dentist regularly Recognising that, for many years at least, most dental surgeons will be occupied mainly in dental repairs, Mr G H Leatherman [1] bases his scheme of preventive care on the employment of women dental ancillaries, or " hygienists," who would undertake scaling and polishing, and would help to instruct patients or parents in the elements of oral hygiene and home treatment Whereas adults, and possibly adolescents, should be seen first by the dental surgeon, who would refer the patient to the hygienist for any minor treatment required, Mr Leatherman thinks that for the very young the sequence should be reversed, because it is psychologically better for the child to be introduced to dental care by a woman He recommends that polishing of the teeth, mouth charting, and the taking of " wing bite " radiographs should be done by the hygienist before the child goes to the dental surgeon for detailed examination and treatment This proposal, however, when he made it before the British Dental Association at Birmingham was strongly criticised,[2] mainly on the ground that diagnosis should precede treatment and that scaling alters the diagnostic picture Mr A F Stammers did not regard scaling as by any means minor dental work it was, he said, the most important thing a dental surgeon could do for his patient Mr E Davies-Thomas, at the Children's Hospital, Birmingham, had made a rule that nobody should talk to the child except himself, and in this way he established a personal understanding

In the care of the teeth at home, Mr Leatherman believes that the basic need from childhood is to prevent gingivitis, and, where gingivitis and its sequelæ have developed, to see that the causes are removed and the supporting structures rendered healthy The patient should be made to understand that the supporting structures of the teeth require as much attention as the surfaces of the teeth themselves, and to this end the term toothbrush should be changed to mouthbrush He favours the use of a mouthwash of full strength hydrogen peroxide (10 volumes), or ' Milton ' (1 part to 4 parts water), or sodium chloride and sodium bicarbonate ($^1/_2$ teaspoonful of each in half a glass of warm water) The teeth and mouth are brushed first thing in the morning and last thing at night with salt powder, or a powder of urea and ammonium , though what really matters is not what is on the brush but how and when the brush is used The brush of choice, according to Mr Leatherman, is one of natural bristle, of medium consistence, 6–8 rows long, the bristles being all of the same length , and more than one brush is necessary, for each should be allowed to dry for at least 24 hours after use. He would have us all clean our dental spaces with wooden sticks or dental floss, and some people should massage the interdental epithelium with a wooden stick. At each mouth cleaning the gums are massaged with the fingers, and the session ends with a mouthwash.

BLEEDING AT OPERATIONS

PERSISTENT oozing of blood during an operation may cause nothing worse than irritation and delay—in itself the loss of blood is not often serious nowadays, when it can easily be made up by transfusion—but it may obscure the surgeon's view and lead to damage of important structures, or by forming a hæmatoma it may delay healing and encourage infection. Surgeons and anæsthetists are inclined to blame each other for such oozing, and almost every anæsthetic agent has at some stage of its career been accused of increasing the bleeding tendency; so the subject has been keenly studied. It seems to be generally agreed that cyclopropane encourages bleeding, though whether this is a direct effect of the gas or a result of the absorption method of administration or of the presence of excess of oxygen is uncertain. Ether is also suspect, because, except in very deep anæsthesia, it stimulates cardiac and respiratory activity and dilates the peripheral vessels. Apart from drug action, bleeding can be aggravated by respiratory obstruction sufficient to raise the venous pressure, and also by breathing excessive amounts of carbon dioxide, whether this comes direct from the cylinder or from a faulty absorber or mismanaged anæsthetic apparatus. Then the surgeon himself may be responsible—for example, he can obstruct the venous return by leaning on the patient, or with his bandages, or, in tonsillectomy, with the tourniquet-like straps of his gag jack.

Two methods of anæsthesia have long been noted for a striking absence of bleeding—chloroform and spinal anæsthesia. Their common feature is that they usually cause a considerable fall in blood pressure. This effect has lately been developed in several directions to reduce bleeding, the two main techniques being (1) high spinal anæsthesia[1] extensive enough to cut off all the sympathetic outflow, and (2) the injection of drugs of the methonium group which act selectively on the sympathetic ganglia.[2] Both of these will produce a profound fall in blood-pressure and ensure a bloodless field for the surgeon. In brain surgery, where bleeding is particularly apt to be troublesome, there is an additional factor—intracranial tension, on which ease of access and the avoidance of surgical trauma largely depend. Intracranial tension is in turn dependent on arterial blood pressure; so by reducing the B.P. it is possible both to control bleeding and keep the intracranial tension low. At Edinburgh Royal Infirmary Bilsland[3] has attained this end with the technique introduced by Gardner[4] in the U.S.A. as "controlled induced hypotension by arteriotomy," an adaptation of the method used experimentally for inducing shock in animals. In this, blood is rapidly withdrawn through a cannula in the radial artery until the desired reduction of B.P. is attained. The blood is run into a reservoir, from which, usually towards the end of the operation, it is returned to the patient by the same route, simply by raising the pressure in the reservoir to above the patient's systolic B.P. In 63 craniotomy cases a B.P. of under 100 mm. Hg has been maintained for up to 6 hours by withdrawing 300–2600 ml. of blood, and only one death could be put down to the hypotension.

Last year Dr. Enderby[2] published in these columns his preliminary results with "controlled hypotension," attained with penta- or hexa-methonium iodide or tetraethylammonium chloride, supplemented by a careful use of posture. The technique, though based on that described by Griffiths and Gillies,[5] was exploratory; nevertheless, Enderby obtained a satisfactory reduction of bleeding in about half of his 85 cases, and the ill-effects were nil. In this issue (p. 663) he and Dr. Pelmore report subsequent experience. Using hexamethonium only, with posture when possible, the proportion of successes has risen to 85% in 250 cases. In fenestration, where the slightest bleeding at the wrong place reduces the chances of success, Dr. Hughes (p. 666) has lowered the systolic B.P. to 75–80 mm. Hg with pentamethonium and posture (plus pentothal and pethidine, "the four P's") and produced a completely bloodless field with no ill effects in 10 cases. But, as several speakers emphasised at the Royal Society of Medicine discussion on March 2, this is not a technique for the inexperienced or inattentive: unless the anæsthetist can keep a constant eye on B.P. and pulse, the behaviour of vessels at the operation site, colour changes, and the state of the peripheral circulation, he had better be content with preventing venous congestion, ensuring a free airway, and the other classical methods of minimising bleeding.

"FAMILY DOCTOR"

THE public appetite for information about medicine is so insatiable as to seem a little morbid, and in fact it is evidence of a deficiency disease. People ingest masses of information, supplied from various sources, in the hope of getting the small amounts of knowledge they need for bodily and mental efficiency. Often this knowledge is of a kind they could get in a few minutes' leisurely conversation with a trusted general practitioner; but for one reason or another they have not got it. In producing a journal that will supplement the efforts of clinicians, educationists, and publicists to meet the large and legitimate demand for sound instruction, the British Medical Association has chosen the title *Family Doctor*, and the editor, Dr. Harvey Flack, aims at making it friendly and dependable, like the good G.P. In a letter introducing the first issue, Dr. Hugh Clegg, editor of the *British Medical Journal*, says that the title "may remind you that the doctor's main concern is to make and keep people well," and he hopes that the new magazine will help everyone to lead a healthy and happy life—"by telling the reader all the medical profession knows about the rules of health for men and women, boys and girls, and for babies." Lord Horder, in a message of encouragement entitled Health is Your Right, speaks of the difficulty caused in this country by medical writers wanting to preserve their anonymity, whereas the newspapers have wanted "not only the 'story' but the signature and, for preference, the photograph also, of the writer." In this demand the newspapers have reflected the opinion of the public who like to know that the person addressing them is an authority; but the difficulty will be largely overcome if readers can feel that, though an article bears no signature, it comes to them with the imprimatur of over 60,000 members of the B.M.A.[6] The success of the American Medical Association's popular magazine *Hygeia* (now called *Today's Health*) is an encouraging precedent, and we congratulate the *B.M.J.* on the birth of this seventeenth child, which will be the public relations officer for its more academic brothers and sisters.

LORD ADDISON

IN his new office as Lord President of the Council, Lord Addison will find himself on largely familiar ground; for the Privy Council is responsible for the General Medical Council, with which his name is registered, and the Privy Council also has under its ægis the Medical Research Council, of which he has been chairman since 1948. Lord Addison remains leader of the House of Lords.

What of resuscitation? Light cradles, heated sleeping-bags, and friction are less effective than rapid rewarming by direct immersion in water at temperatures of up to 50°C, maintained until peripheral vascular spasm is dispelled. Characteristically, the subject gives a sharp outcry, and then the laboured respiration and muscular rigidity disappear. With brisk rubbing and wrapping in warm blankets the temperature is restored to normal in about three hours.

MEDICAL SECRECY AND ABORTION

IN our leading article of Feb. 24 we drew attention to the legal safeguards which foreign systems, in contrast to the common law, have established to protect confidential communications between doctors and their patients. Happenings in two towns of Western Germany at the end of February show that even these measures to prevent breaches of medical secrecy may not go far enough. They also illustrate how jealously the public on the Continent resist any attempt to whittle down, by official action, what they have come to regard as a fundamental right of the individual.

Under a statute of 1935, re-enacted in 1946–47, practitioners in Western Germany have to notify to the public health authorities, for the purpose of registration and statistics, any abortions among patients under their care. There seemed to be no danger in such action until it occurred to the public prosecutor of the town of Weinheim (Baden) that the information thus assembled might be useful for tracking down professional abortionists, whose activities have lately increased. The prosecutor asked the local health authority to give him a copy of the relevant list of women treated for hæmorrhages, &c., during the past six months, and in due course the police were told to summon and interrogate the women named in the list. Perhaps in an excess of zeal, the local chief of police ordered a raid during which some 200 women and girls from the town and neighbourhood were taken in vans to the police station and kept there several hours for questioning and further investigation, on no other ground than that they had been treated within the last six months for miscarriage.

How far this measure succeeded in its purpose is not yet known, for this aspect of the affair has been submerged by a wave of protests from the doctors of the district and from the public. Concern has been aroused all over Germany, particularly since it became known that a similar attempt to get evidence of criminal abortions from official returns of miscarriages had been made by the police at Garmisch (Bavaria). In its indignation over the high-handed action of the police, the German press has not lost sight of the wider principles involved, and much of the outcry has been directed against the public health officials for their "gross breach of medical secrecy" in passing the list of names to the public prosecutor. The local medical organisation has advised its members to suspend all notifications of abortion until the legality of the recent police action has been investigated, and an information has been laid against the health officials concerned for breach of medical and official secrecy. This step has been endorsed by the medical chamber of the Land, which demands new legislation to provide legal safeguards against such breaches of medical secrecy, if the present rules should be found insufficient. After this sharp reaction of public and medical opinion in Western Germany such attempts to circumvent medical secrecy are not likely to be repeated, the more so since German law clearly says that in no circumstances can such a breach be ordered even for the purpose of pursuing punishable conduct.

In this country the duties of medical practitioners in relation to cases of criminal abortion which have come to their knowledge in the course of treatment were the subject of a resolution passed by the Royal College of Physicians in 1916. After emphasising "the moral obligation to respect the confidence of the patient," this advised the practitioner to urge his patient to make a statement to the police; but if such a statement is refused, he is under no legal obligation to take further action and should continue to treat the patient. It is less easy to give any definite answer to the further question which the incidents in Germany may raise here—namely, whether the records of patients and treatment which have to be forwarded to the local executive council under the National Health Service regulations, and the written clinical information which may be requested by the medical officer of health, are, in theory or even in practice, open to similar misuse. There is, however, some authority for suggesting that, if the Government department concerned were to object to the revelation of such documents to the police, the courts would uphold the objection on the ground that the papers are protected as State documents.

CARE OF THE TEETH

THOUGH its causes lie chiefly in diet, much dental caries could be prevented or checked if people could be induced to keep their mouths clean and see a dentist regularly. Recognising that, for many years at least, most dental surgeons will be occupied mainly in dental repairs, Mr G. H. Leatherman[1] bases his scheme of preventive care on the employment of women dental ancillaries, or "hygienists," who would undertake scaling and polishing, and would help to instruct patients or parents in the elements of oral hygiene and home treatment. Whereas adults, and possibly adolescents, should be seen first by the dental surgeon, who would refer the patient to the hygienist for any minor treatment required, Mr Leatherman thinks that for the very young the sequence should be reversed, because it is psychologically better for the child to be introduced to dental care by a woman. He recommends that polishing of the teeth, mouth charting, and the taking of "wing bite" radiographs should be done by the hygienist before the child goes to the dental surgeon for detailed examination and treatment. This proposal, however, when he made it before the British Dental Association at Birmingham was strongly criticised,[2] mainly on the ground that diagnosis should precede treatment and that scaling alters the diagnostic picture. Mr A. F. Stammers did not regard scaling as by any means minor dental work: it was, he said, the most important thing a dental surgeon could do for his patient. Mr E. Davies Thomas, at the Children's Hospital, Birmingham, had made a rule that nobody should talk to the child except himself, and in this way he established a personal understanding.

In the care of the teeth at home, Mr Leatherman believes that the basic need from childhood is to prevent gingivitis, and, where gingivitis and its sequelæ have developed, to see that the causes are removed and the supporting structures rendered healthy. The patient should be made to understand that the supporting structures of the teeth require as much attention as the surfaces of the teeth themselves, and to this end the term toothbrush should be changed to mouthbrush. He favours the use of a mouthwash of full strength hydrogen peroxide (10 volumes), or 'Milton' (1 part to 4 parts water), or sodium chloride and sodium bicarbonate ($^{1}/_{2}$ teaspoonful of each in half a glass of warm water). The teeth and mouth are brushed first thing in the morning and last thing at night with salt powder, or a powder of urea and ammonium; though what really matters is not what is on the brush but how and when the brush is used. The brush of choice, according to Mr Leatherman, is one of natural bristle, of medium consistence, 6–8 rows long, the bristles being all of the same length; and more than one brush is necessary, for each should be allowed to dry for at least 24 hours after use He would have us all clean our dental spaces with wooden sticks or dental floss, and some people should massage the interdental epithelium with a wooden stick At each mouth cleaning the gums are massaged with the fingers, and the session ends with a mouthwash

[1] *Brit dent J* 1950 89, 119

[2] *Ibid* p 125

The magnitude of this change is best appreciated in its reflection in the medical press Table I shows the number of articles in THE LANCET classified according to the number of contributors under the title of each, that is to say whether they were written by one, two, three, &c , contributors I have excluded articles which are essentially monographic, such as memorial lectures and presidential addresses, and also short clinical notes

These figures show that multiple authorship, uncommon fifty years ago, now exceeds single authorship

Table II shows the relative numbers of medical and lay contributors

TABLE II—MEDICAL AND LAY CONTRIBUTORS

Contributors	Year		
	1899	1924	1949
Medical	291	273	499
Lay	2	16	85
Ratio of lay to medical		1 17	1 6

Lay authorship, once a rarity, has increased at an accelerating rate and now forms a substantial part of the total If I had included the large number of postscript acknowledgments the figures would have been even more striking

Of the two lay contributors in 1899 one was a physiologist, the other a bacteriologist The occupations of those in the other years were

1924	
Chemists and biochemists	5
Physiologists	5
Botanist	1
Physicist	1
Protozoologist	1
Not stated	3
Total	16
949	
Chemists biochemists pathological and bacteriological chemists	39
Bacteriologists	8
Statisticians	4
Physicists	3
Pharmacologists	3
Physiologists	2
Biologists	2
Accountants	2
Laboratory technicians	2
Nurses	2
Pathologist	1
Medical artist	1
Engineer	1
Lecturer in experimental method	1
Cerebral palsy therapist	1
Holders of science degrees subjects not stated	13
Total	85

The 1949 list shows the wide range of occupations involved, the predominance of chemists, and the admission of technicians to partnership in publication

LAY PARTICIPATION AT ACADEMIC LEVEL

The extent of lay participation in research and teaching needs no emphasis It is, however, worth pointing out that a medical qualification is no longer essential for the directorship of the National Institute for Medical Research or for professorships of physiology, biochemistry, or even anatomy Of the 35 research units of the Medical Research Council no less than 9 are under lay directors Lay participation has become essential to almost every research team It sometimes provides the inspiration and it always exerts a disciplinary influence on a subject peculiarly prone to intellectual delinquency To change the metaphor, the concrete of clinical experience, formerly sufficient for the structure of medical progress, must now be poured round the iron skeleton of science

As the influence of the laboratory increases, individualism declines The discovery of the plantar reflex was complete and perfect in itself and required only one person , the discovery of a new drug is only the beginning of a process with endless ramifications involving a countless number of persons Sir Alexander Fleming, who in the medical field has made the greatest individualistic discovery of our day, has pointed out that the production of a new antibiotic involves in turn the biologist who discovers it, the chemist who purifies and if possible synthesises it, the pharmacologist who investigates its properties, the physician who assesses its therapeutic effects, and the pharmaceutical manufacturer who makes it in quantity Note that the physician takes fourth place The unlimited fecundity of science and the relative sterility of clinical observation make it certain that in the higher branches of medicine the worth of a medical qualification will undergo a further decline

HOSPITAL PERSONNEL

The value of a medical qualification is, however, more seriously affected by the growth of the auxiliary, administrative, and clerical staffs To illustrate this growth I give in table III the figures for Addenbrooke's Hospital, Cambridge

From the figures for 1950 a small deduction should be made for work in connection with satellite hospitals Neglecting this we see that in fifty years, though beds have only doubled, the labour involved has increased 7 times , the medical staff 12 times, and the nursing staff 5 times, while the auxiliary and administrative staffs have grown from almost nothing It may appear surprising that in 1900 one person should have sufficed for administration , but Dr G S Haynes, who was then house physician and who happily is still with us, tells me that the secretary, a solicitor practising in the town, was paraplegic and was wheeled into the hospital for board meetings All the administration, such as it

Points of View

THE ECONOMIC VALUE OF THE DOCTOR

FFRANGCON ROBERTS
M A, M D Camb, F F R

THE most significant feature of the threatened dismissal of the registrars is that under a Government committed to full employment the first departure from this principle should affect one of the higher-wage groups While hoping for a satisfactory solution of the problem we may profitably inquire whether it is an isolated malaise (teething trouble, to use the current jargon) due to special circumstances unlikely to recur, or whether it is the first symptom of a condition likely to become recurrent or chronic To find the answer we must examine the effects of medical and social evolution upon the economic value of the doctor to the community

The counsel given by the writer of *Ecclesiasticus* and the designation of medicine as a noble and learned profession may persuade us that the doctor has always been held in high honour, a state which the march of medical science cannot fail to enhance I propose to show that this view is mistaken, that in the doctor's prestige three periods can be discerned a long period when it was low, a short period when it rose very rapidly, and a third, the present, period when it is undergoing a *relative* decline

The attitude of the public on this point is mercurial and unreliable It fluctuates, according to circumstances, between extremes of emotional gratitude and hostile criticism The threat to the registrars was bewailed by one of our popular newspapers as the destruction of the hopes of "the brilliant young men and women," destined for Harley Street Such sentimental adulation, however, is one of those psychological devices invented by society to create a feeling of security When someone is going to remove your stomach you feel safer if you can deify him The opposite to this idolatry was evident in the unsympathetic attitude taken during the passing of the National Health Service Bill by a section of the press from which many had expected unflinching support

THE PERIOD OF LOW PRESTIGE

The history of medicine, as usually recounted, is misleading in that it concentrates on the high lights—on those who made notable advances in medical science, on those who gave valued personal service to their sovereigns, and on those who aped the flamboyant manners of high society These, however, were very few and were not typical of their profession The gold headed cane was conspicuous enough in Pall Mall to inspire the satirical brush of Hogarth, but that it was the customary adornment of doctors in general is hardly credible The surgeon was someone to be "fetched" when occasion arose Unlike the Church, the Services, and the Bar, medicine was always completely devoid of privilege, patronage, and sinecures, and was therefore never considered a suitable outlet for the energies or lucrative indolence of the cadets of the aristocratic families

To the wits of all times, from Aristophanes to G B Shaw, the doctor has been a favourite butt In Victorian fiction he cuts a sorry figure Mr Bob Sawyer and Mr Benjamin Allen of *Pickwick Papers* are obviously caricatures, as are Surtees's Dr Roger Swizzle and Dr Sebastian Mello, and Trollope's Sir Omicron Pie and Dr Fillgrave But even in his more serious mood Dickens depicts the doctor as kind hearted but fussy and incompetent George Eliot, who acquired a knowledge of medicine unequalled by any other novelist save possibly Flaubert, presents the provincial doctor in a more dignified light Nevertheless one of the characters in *Middlemarch* says

> 'Mr Brooke says he is one of the Lydgates of Northumberland, really well connected One does not expect it in a practitioner of that kind For my part, I like a medical man more on a footing with the servants they are all the cleverer I assure you I found poor Hicks' judgment unfailing, I never knew him wrong He was coarse and butcher like but he knew my constitution"

No, doctors were quite humble members of society, and their neglect of sanitation, which, though well within their competence, they left to a layman to reform, is alone sufficient to show that they deserved no better consideration

THE PERIOD OF RISING PRESTIGE

This situation was radically transformed by the discovery of the microbial origin of infection, with its corollary, antiseptic surgery, reinforced by the earlier discovery of anæsthesia For the first time in its history the medical profession became a power in the land The doctor who in Fildes's famous picture could only sit in helpless contemplation of his patient gave place to one who could save life dramatically by operation or quietly but no less surely by prophylaxis At the same time he acquired great civil powers He could influence legislators, condemn houses, close schools, and deprive citizens of their liberty by putting them in quarantine The new knowledge, combined with the high standard of refinement and cleanliness required in its practice, gave to the sons, and later the daughters, of the rising middle class an opening with unlimited possibilities which the more static professions lacked New medical schools were opened, the curriculum became more exacting and higher qualifications were instituted This period can be defined as the period during which the new gifts of science could be exploited by the doctors individually, with little help from their colleagues and none from lay sources apart from nurses and pharmacists Doctors stood alone in their glory, perched high above the city like muezzins on their minarets

THE PERIOD OF RELATIVE DECLINE IN PRESTIGE

Since the early 1920s, however, there has come over the scene another change the importance of which has been overlooked The progress in the knowledge of disease and in the complexity of technique has enforced an increasing degree of collaboration Individualism is giving place to team work This in itself would be of no great moment were it not for the fact that such collaboration is becoming progressively lay in character (I use the word lay as meaning the absence of a medical qualification) The contributions of science have now passed beyond the stage when they can be handed over to the doctor On the higher plane their complexity has enforced their retention in the hands of the lay scientists and on the lower plane their widespread application has enforced their delegation to technicians By the limitations of his training in the one case and by the exigencies of practice in the other the doctor has become incapable of applying them himself

With regard to advertised vacancies, over 95% of the recommendations by executive councils were accepted.

Dr D F **HUTCHINSON** said that general practitioners were not happy about the service. They were making a just demand for improved remuneration; but the greatest source of discontent was the administration, which did not enable them to give the best possible service; they felt that they were tied with red tape and that the administration should be simplified. In England and Wales the delay in filling practice vacancies was now shorter, but still greater speed might be achieved by following the example of Scotland, where appeals against decisions in filling vacancies were heard by the Medical Practices Committee. As to the classification of areas, practitioners thought this was too rigid, and that the Medical Practices Committee gave insufficient weight to local opinion. Dr Hutchinson agreed about the need for cooperation between the three main divisions of the service; and from his experience as a member of both the Central Consultants and Specialists Committee of the B.M.A and the General Medical Services Committee, he denied the existence of antagonism between practitioner and specialist. Nevertheless in some areas the practitioner was not given a proper opportunity to place his views before hospital bodies.

Sir **WILLIAM MARSHALL** was impressed by the difficulty of young doctors in establishing themselves in practice. The second world war, with the associated rise in income tax had made it almost impossible for the young graduate to purchase a practice unless he had substantial financial backing; even now, with sale and purchase of practices abolished, he might still have difficulty in buying a house, car and so on. Sir William was impressed, too, by the number of men, aged 30–40 and perhaps married, who applied for a place in one practice after another. Unless he gained an assistantship with a view to partnership, the outlook for him was almost hopeless. Related to this problem was the size of lists. He himself was convinced that a doctor with the maximum of 4000 patients could not give reasonable service and have leisure and a chance to keep himself up to date. Even with a list of 3000, on a basis of 5 items of service per patient per year the doctor would be giving 30–40 items per day and up to 70 in the winter. He hoped that any additional money would be used to aid the practitioner with small lists.

Dr H S **HOWIE WOOD** suggested that the two main causes of discontent among practitioners were (1) the Minister's failure to fulfil his promise to fix remuneration; and (2) the practitioner's reduced status. Young men seeking to enter practice should make full use of the trainee assistant scheme.

Mr A N **WRIGHT** president of the Executive Councils Association (England), challenged Dr Rogers's assessment of the executive-council machinery; and he agreed that the method of filling practice vacancies should be revised, with appeal only to the Medical Practices Committee.

Dr J L **McCALLUM** said that patients realised they were getting good service from practitioners; but they noticed that the doctor was hurried. This haste could not go on for ever: the patient would not put up with it and the doctor's health could not stand it; the wastage rate among practitioners was rising. The doctor should be given more time by providing him with ancillary help and suitable premises. "The doctor's best equipment is his time."

Mr A J **FIELDER** held that the average person, seeing his doctor with one new car after another, was not convinced that he was not faring well. The doctor, it perhaps seemed, was just in doubt whether he wanted to be a Civil Servant. If doctors wanted better conditions they must persuade the public that there was more to it than this.

More than one medical speaker referred to the difficulty created by thoughtless patients who applied needlessly late in the day for a visit; this meant that the doctor had to cover the same ground a second time, and he had no way of countering such heedlessness.

Answering questions, Dr **ROGERS** observed that the number of young men seeking to enter practice had fallen off a little; but the number would soon be swollen by ex-registrars. To place them suitably, executive councils and regional boards should possibly work together. The immediate need was for increase in the capitation fee for the first 1000 patients; this increase should apply only to principals, for otherwise there was little incentive to take on a partner rather than an assistant.

The Hospital Administrator

Mr J **CRAWFORD FIELD** suggested that every job can be divided into policy (what shall be done) and execution (actually carrying out the work). With simple tasks both these functions could be exercised by the same person; but in a more complicated procedure, where several people took part, a third function, administration, was needed to coordinate their efforts. In a hospital, policy was settled by the chairman and the committee, and execution was carried out by the different departments. But who was to be administrator? In a multicraft organisation like a hospital, if the executive parts were to work together happily, it must be clear that administration was not the prerogative of one of the sections. This ruled out, in his view, the medical administrator with clinical duties. Similarly the administrator should stand apart from staff specialising in finance, supply, and maintenance. At present many hospitals and groups of hospitals had no true administrator, but the struggle for power between the different departments would make the appointment of a coördinating officer inevitable. Mr Field believed the position of the administrator was stronger if he had no part in policy making, and the staffs of the different services did not regard him as responsible for the decisions taken by the chairman and committee.

Dr T **ROWLAND HILL** affirmed that the administrative problems of the doctor had been enormously increased by the suddenness with which the National Health Service was introduced. Medical organisation and practice, especially in large hospitals, were so intricate and delicately balanced that efficiency was easily impaired. To get the best doctor, he must in his work be both free and trusted. Save us, Dr Hill cried, from the purely technical doctor who becomes a subordinate officer in an administrative machine with no sense of independent professional and ethical authority. We would not achieve a contented service by creating a highly disciplined authoritarian organisation in which most of the staff felt they had merely to obey instructions. For this reason Dr Hill warmly advocated joint consultation with all grades of responsible staff, which he believed had been so far insufficiently developed in the National Health Service. He deprecated the present practice of obtaining advice not from the chosen representatives of the profession but from panels of experts chosen by the administrative department concerned.

Dr E B **BROOKE** agreed with Florence Nightingale that administration is the enlightened pursuit of economy; and true economy, he pointed out, was getting value for your money. The hospital administrator, he suggested, should be a good housekeeper. But a good housekeeper should have control of the housekeeping money, and he thought it would be better if the savings of hospital management committees could be reflected in local benefits. Another problem of hospital administration

4. Is the medical curriculum designed to provide a philosophic ascendancy sufficiently powerful to maintain control over events and sufficiently stable to withstand the changes which time brings?

It will no doubt be objected that to ask these questions strikes at the roots of medical freedom. But economically medicine never has been and never will be free. Those who imagine that the nationalisation of medicine gives them licence to do and have what they like will soon realise their error. Medicine, having acquired the capacity for unlimited procreation, becomes subject to the Malthusian law: the pressure which it exerts against its means of subsistence will, if we are not careful, inevitably lower its standard. We make a great mistake if we imagine that its tension against the inexorable resistance of economics will be unaccompanied by internal disturbances. It will develop the fretfulness of frustration.

For what is to count in the medicine of the future? The qualities and experience which should result from a medical training, or the test tube and the machine? Is medicine to degenerate into mass production in which technicians multiply and leadership lies in the hands of those members of the profession with a flair for organisation and committee-work? If so, it is obvious that the State cannot at the same time continue to pay a number of four figure salaries which would drive a commercial concern to bankruptcy.

We are concerned not with what is best for ourselves but with what is best for medicine. At the same time we must remember that it takes at least six years to train a doctor and about fifteen to train a specialist. We cannot foretell what medicine will be like in 1966, but we can confidently predict that at the present acceleration of progress it will differ from the medicine of 1951 far more than the medicine of 1951 differs from the medicine of 1936. We therefore owe it to those who come after us at least to make some attempt to read the signs of the times and to ask ourselves what we are doing and why we are doing it. Unless man's capacity to induce changes in his environment is accompanied by an equal capacity to adapt himself to those changes he will not be master of his destiny.

PROBLEMS OF THE HEALTH SERVICE

LONDON CONFERENCE

REPRESENTATIVES from the various branches of the National Health Service were brought together—for the first time in England—at a conference held in London last week by the Institute of Public Administration. The chairman was Mr HENRY LESSER.

General Practice

Dr A. TALBOT ROGERS said that the executive councils had taken over the offices, staffs, methods, and outlook of the old insurance committees. Initially this was an advantage, but this borrowed administration was "not so well suited to resolving in any radical manner the newer problems peculiar to the changed conditions of a service now available to all, and provided by doctors whose traditional methods of entering and leaving practice had been abruptly abolished." Many had hoped that the executive council might have become a forum for exchanging lay and professional views on policy and planning; but the mass of detailed day to day work in which the councils and their officers were immersed had almost everywhere confined them to a managerial rôle. Consequently, on the medical side, local medical committees had had to work out for themselves the solutions to new problems, and when in difficulty to apply for guidance to their own central committee—the General Medical Services Committee.

As to entry into practice, the Medical Practices Committee had hesitated to close areas to new entrants unless these were most manifestly over doctored.

> It has often had to resist local arguments in favour of closure of areas, and not infrequently has had to upset on appeal the choice of a successor for a practice, or the decision that no successor was needed. In many of the cases where it has done this it has had to act, not from exact local knowledge but rather from rule of thumb methods based upon calculations of the numbers of doctors and the numbers of the population. Some of the committee's decisions have undoubtedly given rise to heart burnings among the local medical committee members who feel that if they, with full local knowledge and acting as carefully, impartially and disinterestedly as they can have come to a decision this decision should not lightly be upset by a remote central committee.

As to the tribunal which dealt with serious disciplinary offences, the main reasons for dissatisfaction were (1) the very long delays in some cases between commission of the offence and the tribunal's decision, and (2) the revelation in certain cases of the defendant's name and place of practice, even though the case against him had not been established. Many doctors remained dissatisfied, too, that no provision was made for an appeal to a court of law.

One weakness of the Act was that it sectionalised the administration of the service, and provided little, if any, local means of liaison between the administration of the hospitals, the local authority health services, and the general medical services. Commonly local medical committees had gone some way towards overcoming this weakness by coopting the local medical officer of health. Similarly, a place had been found for a general practitioner on the health committee of some local health authorities. One example of the value of such cooption was in the provision of medical care on new housing estates. All too often a new estate was developed "with no agreed conception of how and where medical care should be provided being reached by the health authority, the executive council, and the local medical committee, all of whom are concerned."

Professional members of the boards and committees administering hospitals were almost all consultants, and this, practitioners felt, often resulted in a failure by these boards and committees to understand the practitioner's point of view and how much sound advice he could give on what would best satisfy his patients' needs. The problem of the over provision of registrars could not, it seemed, be solved satisfactorily without full and continuing consultation between bodies administering the hospitals and those administering general practice.

Dr W. E. DORNAN, chairman of the Medical Practices Committee, insisted on the need for the stabilising influence of this central body, which was able to get a comprehensive picture denied to local committees. The committee had never refused admission to local lists against the advice of executive councils, but in the fringe areas it had often admitted doctors against the advice of councils. The committee was concerned, not to protect doctors in established practice, but to preserve the greatest freedom for any doctor to practise where he would, subject only to the interest of the public being served. Though the right to sell goodwill had been lost, many of the best features of ownership had been retained, and the committee had jealously preserved the right of principals to nominate partners and assistants. Over half the appointments to vacancies in established practices were now made in complete agreement with executive councils, local medical committees, and local doctors.

either a separate block or appropriate separate ward units in which patients are looked after by their own general practitioners I am also in favour of selected general practitioners acting as part time assistants to consultants "

As to lay and medical hospital administration, either system "can work admirably if the officer is a man of high ability and suitable personality" But "*I doubt* whether hospital administrators of the necessary quality are likely to be recruited and retained under present conditions "

> " In these days of huge hospital regions and large hospital management groups there is not sufficient recognition of the fact that the local administration of one hospital of 200–800 beds requires a man of very high ability and suitable personality, and that this is more important than the question whether he should be medical or non medical — the more I have seen of organisation of hospital and other health services, the more I am convinced that in the end the quality of service depends on the quality of the individual in local charge of its various subsections—for example, the administrator of the individual hospital '

Finally, with regard to maternity beds, for the individual family institutional care was much cheaper than domiciliary care, and this anomaly should be corrected because it increased the demand for institutional care The hospital service, having to refrain from unnecessary expansion, might wish to abandon schemes for extending institutional midwifery to deal with 75% or more of all births and be content with a target of 40% or so, according to local conditions

Public Health

World Typhoid Survey

ONE of the legacies of the late war was a recrudescence of enteric fever throughout Europe A survey published by the World Health Organisation in 1948 noted that the "safe areas" had been reduced to the United Kingdom, Switzerland, and the Scandinavian countries, and that in other areas the position was wholly unsatisfactory and showed no signs of improvement The latest survey published by W.H O shows that since 1947 there has been an unexpected reduction in the number of cases in Europe, but not in Africa, America, Asia, and Oceania

In Europe the number of cases fell from 162,000 in 1947 to 118,000 and 124,000 in the two following years, and an estimated 105 000 in 1950 In 1948 the greatest improvement was in Austria Germany, Finland Italy and Poland, while in Belgium Greece, Luxembourg and the United Kingdom the incidence remained the same In 1949 the downward trend continued except in France and Spain where there were severe outbreaks and in 1950 the position was still improving despite moderately severe epidemics in Turkey and Yugoslavia and minor ones in Sweden and Switzerland

In the other continents the total incidence has remained the same In Africa the decline in the number of cases in Algeria Madagascar Mauritius Morocco, and Tunisia was balanced by a steady rise during the three years, in Northern and Southern Rhodesia and a considerable increase in the number of notifications in Egypt and Kenya during 1948 and 1949, and in the Union of South Africa in 1949

For the whole of the American continent the total number of cases remained the same There was an increase of incidence in Colombia in 1948 and 1949, and a decrease in Costa Rica Cuba Haiti, Jamaica, Peru and St Vincent The United States had by far the fewest cases in proportion to the size of its population

Of those countries in Asia for which figures are available the majority showed an increased incidence of enteric fever they include Afghanistan Ceylon Cyprus Iraq Iran, Israel, Malaya, and Syria Japan was an exception, for there was a spectacular drop in the number of cases from 1947 to 1950 In the Fiji Islands the incidence rose in 1947 and 1948 and fell again in 1950

In England Now

A Running Commentary by Peripatetic Correspondents

OUR province extends from the incisor teeth to the anal sphincter, and strange things come our way Last week we had our bezoar It came to us in a quiet unassuming housewife, and our physician first spied it through his gastroscope, so we all queued up to cast an eye Our radiologist was delighted, he showed it in his films, and even pushed it up into the pouch of the woman's diaphragmatic hernia We showed her to the clinic and one student responded with the diagnosis of "a hairy ball in the stomach"

Such was the splash it made in our hospital, the ripples reaching the outside world were far more decorative In the patient's home village the thing was a tropical beast (derivation foreign body—foreign beast—tropical beast) The houseman in a neighbouring unit heard their lady-help telling his mother that it was four inches long, with a pointed beak, a furry coat, and short legs The village postman knew it had a long neck, for surely it reached up for food when hungry The patient's own doctor told us that everyone in the village knew how we had fed it for days on little crusts of bread dangled on a string down a tube and then one day had poisoned the bait and that was its end

With his more direct approach our chief opened her stomach, and there are some who say that it took wings and flew round the theatre, chased by the anæsthetist with an ethyl chloride spray At last we had it out and sent it to the Professor of Botany, who laid the ghost . the undigested skin of a citrous fruit—not a trichobezoar but a citrobezoar The answer was in fact a lemon

* * *

I am a confirmed air-traveller, and I travel B O.A.C. whenever possible, but I wish the corporation would apply a little spit and polish to their service I have just returned from a flight to the Far East, mainly by B O A.C but using other lines now and then, which gave me an opportunity for comparisons

The B O A C catering is reasonable by our present English austerity standards but inferior to that of K L M or Quantas There is some excuse for this but none for providing different qualities of sherry according to whether you pay for it separately or have it as a "complimentary" drink before dinner, when it is included in the price of the meal

This happened on my flight back from Nairobi by the new and much-vaunted *Hermes* service The sherry I paid for was drinkable, the complimentary sherry was not Incidentally the prices of drinks are extortionate compared with those charged on ships, being the standard English hotel prices Considering that the flights often include night flying, that there may be 40 passengers on board, and that the washing arrangements at most airports are poor, hot water can hardly be called a luxury, and the supply should not be as temperamental as it is, nor should one be expected to make do with paper towels, which are all that some B O.A.C lines provide. Sir Miles Thomas's attempts to make the corporation pay are no doubt laudable, but stinginess in the toilet department is not a worth-while economy

Some of the airports are still pretty grim Aden was the worst I sampled We touched down there on the flight from Karachi to Nairobi by Air India International and were given a miserable breakfast with execrable tea (no coffee) Malta gave us a reasonable breakfast, but I have yet to meet a bleaker and draughtier spot on a blustery wet December morning than the Malta airport Imagine a derelict railway waiting-room in some isolated corner of this country, with canine excreta on the floor, and you will be somewhere near it

Finally—and this applies to several of the airlines I have sampled—when the departure of a plane is delayed, why are the passengers not told the reason? Any passenger who tries to obtain such information from the ground staff can be sure of a rebuff, and this is all the more irritating because the full details are always forthcoming from the crew once the plane is in flight Two years ago we were delayed for hours at Gander on our return absurdity of having to increase administrative costs in order to bring down total outlay could be avoided if doctors, dentists, and opticians worked in publicly provided health centres or clinics "

More fundamental was the basic dilemma of the N H S how with limited resources to meet a potentially unlimited demand for medical care—how to impose a ceiling on "production" when the lid was taken off "consumption" The service was based on the naïve idea that it was simple to decide what was medically necessary, and that all such needs must be met

> ' There are two objections to this view First, there is a large subjective element even in the professional view of what is 'medically necessary,' especially in such matters as buildings, equipment, and ambulance rides If the head of every department of every hospital were to write down his ideal requirements for good work, and all the bills were added up, the present outlay on hospitals might have to be raised three or four times to meet the total Secondly, the subjective element is even stronger in the patient's mind Medical care tends to reverse normal economic laws the supply tends to create the demand, rather than vice versa The priestly function of the doctor, for instance, is capable of indefinite expansion, so possibly is the cosmetic use of spectacles and dentures, and the use of hospitals as hostels for elderly relatives unwanted at home "

For checks that were not merely arbitrary two sets of criteria were required (1) standards of quality of professional work, staffing, accommodation, and other aspects of care, and (2) standards of cost of necessary work efficiently performed

The problem of rational financing was made harder by the fatal division between responsibility for the use of resources and responsibility for providing them, this ran right through the N H S but was most marked in the hospitals The Ministry, lacking any sure means of judging how far their requests were reasonable, had yielded to the fatal temptation to control the affairs of the hospitals in detail The bureaucratic control predicted by the opponents of the N H S had in fact been imposed on the hospitals Economy was possible without this, and it even fostered waste

> "I fail to see how the need for economy justifies these controls By fixing an annual sum not to be exceeded by the hospitals as a whole, the Government has already taken the first step towards making them unnecessary The second step would be to treat this as a pool to be shared among the regions for the time being according to some rough criterion of relative needs of a necessarily empirical kind The third step would be to leave each regional board free within broad limits to share its funds between its management committees as it chooses, the fourth to give the committees a reasonable freedom to manage their own 'block budgets, including a right to save money without forfeiting it Until the development of hospital costing yields reliable means of measuring efficiency and needs, such a system would of course be arbitrary But the present system is not only just as arbitrary it is also bureaucratic and damaging to the whole spirit of the hospital service '

As to checking the public appetite for health service care, the first need was to examine the professional man's position and to remove from his working environment any features tending to deprive him of incentives to economy, or giving him an incentive to be over lenient with his less sensible patients There was, too, a certain scope for more direct measures, including charges to patients

> Generally I think there is a case now for introducing charges in the N H S for 'articles rather than for services but only in cases where without creating a new financial barrier to necessary care charges would result in a real overall economy There is little point in using charges to reduce the public cost of a service if this merely sends up private spending by an equivalent amount That is, I suspect, precisely what would happen if a charge were introduced for board and lodging in hospital '

Ideally, said Mr Lafitte, the whole N H S budget should be directed to securing the rational deployment of all available medical resources It was arguable, too, that one aim should be to build up the "front line" services, so as to screen away from the hospitals and other services at the "rear" the greatest possible amount of work

> " My impression is that such wider issues of strategy are not being sufficiently considered, although the long term fate of medicine in part depends on them, because it is no-one's job outside Whitehall to look at the pattern of needs and resources in medical care as a whole In most places I suspect that they [the hospital authorities] have the most influence in determining the whole pattern and trends of development of the medical care and services The shape they are imposing is, I suspect, derived from their own particular attitude to medical care, which is largely that of the specialist clinicians, and the general trend seems to be for them to claim all the work which interests them and to leave the rest to other agencies If I am right, the budgetary implications may be very great in the long run, since the hospital is the most expensive means of supplying medical care If specialists, general practitioners, and midwives—or 'general' and priority dentists—were all on the same payroll, is it not likely that developments in many places would be going along different lines? It may well be that we shall have neither 'rational planning' nor economical budgeting until the power to allocate funds between the different branches of the N H S is vested in some authority, below the level of central government, which is competent to look at every aspect of the position in a particular place, and is responsible for finding part of the necessary funds from local, not central, sources "

Planning and Coördination

Dr W G **PATTERSON** declared that major hospital planning should be considered by the appropriate local health authority, whose observations might be of great value At present there might be no consultation, not because the board was opposed to it, but because the board and its officers were so overworked that they did not go out of their way to initiate time consuming discussions Formal consultation should be obligatory, but, failing this, a suitable liaison committee should be set up As regards cooperation between board and management committee, Dr Patterson had seen great benefit result where the chairman of the management committee was a member of the board At regional board level administrative officers were at present overtaxed, and he believed that the gravest immediate impediment to an efficient service lay in the risk of a breakdown in the administrative medical and architect organisation of regional boards

Another difficulty was the poor general practitioner representation on regional boards, and Dr Patterson was convinced that this accounted in part for some failure in cooperation between boards and practitioners To secure committee member cooperation, on local matters, between the three branches of the service, each hospital region should have several liaison committees including members of local health authorities, local sanitary authorities executive councils, and hospital management committees, and each liaison committee should preferably cover a population of about 300,000 Officers should also have a local officer liaison committee At regional level there was need for a regional health services liaison committee, including members of the regional board, the board of governors, local health authorities, and executive councils To avoid unwieldy size, local health authorities and executive councils might have to agree to token membership

Observation had convinced Dr Patterson that the best domiciliary general practice was found where practitioners attended patients in a good cottage hospital 'Indeed, I hold that where there is no cottage hospital available the large general hospital should include either a separate block or appropriate separate ward units in which patients are looked after by their own general practitioners I am also in favour of selected general practitioners *acting as part time assistants to* consultants "

As to lay and medical hospital administration, either system "can work admirably *if the officer* is a man of high ability and suitable personality " But "I doubt whether hospital administrators of the necessary quality are likely to be recruited and retained under present conditions "

> ‘ In these days of huge hospital regions and large hospital management groups there is not sufficient recognition of the fact that the local administration of one hospital of 200–800 beds requires a man of very high ability and suitable personality, and that this is more important than the question whether he should be medical or non medical the more I have seen of organisation of hospital and other health services the more I am convinced that in the end the quality of service depends on the quality of the individual in local charge of its various subsections—for example the administrator of the individual hospital ’

Finally, with regard to maternity beds, for the individual family institutional care was much cheaper than domiciliary care, and this anomaly should be corrected because it increased the demand for institutional care The hospital service, having to refrain from unnecessary expansion, might wish to abandon schemes for extending institutional midwifery to deal with 75% or more of all births and be content with a target of 40% or so, according to local conditions

Public Health

World Typhoid Survey

ONE of the legacies of the late war was a recrudescence of enteric fever throughout Europe A survey published by the World Health Organisation in 1948 noted that the "safe areas" had been reduced to the United Kingdom, Switzerland, and the Scandinavian countries, and that in other areas the position was wholly unsatisfactory and showed no signs of improvement The latest survey published by W.H O shows that since 1947 there has been an unexpected reduction in the number of cases in Europe, but not in Africa, America, Asia, and Oceania

In Europe the number of cases fell from 162,000 in 1947 to 118 000 and 124 000 in the two following years, and an estimated 105 000 in 1950 In 1948 the greatest improvement was in Austria, Germany, Finland, Italy and Poland, while in Belgium Greece, Luxembourg and the United Kingdom the incidence remained the same In 1949 the downward trend continued except in France and Spain where there were severe outbreaks and in 1950 the position was still improving despite moderately severe epidemics in Turkey and Yugoslavia, and minor ones in Sweden and Switzerland

In the other continents the total incidence has remained the same In Africa the decline in the number of cases in Algeria, Madagascar Mauritius Morocco, and Tunisia was balanced by a steady rise, during the three years in Northern and Southern Rhodesia and a considerable increase in the number of notifications in Egypt and Kenya during 1948 and 1949, and in the Union of South Africa in 1949

For the whole of the American continent the total number of cases remained the same There was an increase of incidence in Colombia in 1948 and 1949 and a decrease in Costa Rica Cuba Haiti, Jamaica, Peru and St Vincent The United States had by far the fewest cases in proportion to the size of its population

Of those countries in Asia for which figures are available the majority showed an increased incidence of enteric fever they include Afghanistan Ceylon Cyprus, Iraq, Iran Israel Malaya, and Syria Japan was an exception for there was a spectacular drop in the number of cases from 1947 to 1950 In the Fiji Islands the incidence rose in 1947 and 1948 and fell again in 1950

In England Now

A Running Commentary by Peripatetic Correspondents

OUR province extends from the incisor teeth to the anal sphincter, and strange things come our way Last week we had our bezoar It came to us in a quiet unassuming housewife, and our physician first spied it through his gastroscope, so we all queued up to cast an eye Our radiologist was delighted, he showed it in his films, and even pushed it up into the pouch of the woman's diaphragmatic hernia We showed her to the clinic and one student responded with the diagnosis of "a hairy ball in the stomach."

Such was the splash it made in our hospital, the ripples reaching the outside world were far more decorative In the patient's home village the thing was a tropical beast (derivation foreign body—foreign beast—tropical beast) The houseman in a neighbouring unit heard their lady-help telling his mother that it was four inches long, with a pointed beak, a furry coat, and short legs The village postman knew it had a long neck, for surely it reached up for food when hungry The patient's own doctor told us that everyone in the village knew how we had fed it for days on little crusts of bread dangled on a string down a tube and then one day had poisoned the bait and that was its end

With his more direct approach our chief opened her stomach, and there are some who say that it took wings and flew round the theatre, chased by the anæsthetist with an ethyl chloride spray At last we had it out and sent it to the Professor of Botany, who laid the ghost . the undigested skin of a citrous fruit—not a trichobezoar but a citrobezoar The answer was in fact a lemon

* * *

I am a confirmed air-traveller, and I travel B O.A.C. whenever possible, but I wish the corporation would apply a little spit and polish to their service I have just returned from a flight to the Far East, mainly by B O A C but using other lines now and then, which gave me an opportunity for comparisons

The B O A.C catering is reasonable by our present English austerity standards but inferior to that of K L M or Quantas. There is some excuse for this but none for providing different qualities of sherry according to whether you pay for it separately or have it as a "complimentary" drink before dinner, when it is included in the price of the meal

This happened on my flight back from Nairobi by the new and much-vaunted *Hermes* service The sherry I paid for was drinkable, the complimentary sherry was not Incidentally the prices of drinks are extortionate compared with those charged on ships, being the standard English hotel prices Considering that the flights often include night flying, that there may be 40 passengers on board, and that the washing arrangements at most airports are poor, hot water can hardly be called a luxury, and the supply should not be as temperamental as it is, nor should one be expected to make do with paper towels, which are all that some B O.A.C lines provide. Sir Miles Thomas's attempts to make the corporation pay are no doubt laudable, but *stinginess in the toilet department is not* a worth-while economy

Some of the airports are still pretty grim Aden was the worst I sampled We touched down there on the flight from Karachi to Nairobi by Air India International and were given a miserable breakfast with execrable tea (no coffee) Malta gave us a reasonable breakfast, but I have yet to meet a bleaker and draughtier spot on a blustery wet December morning than the Malta airport Imagine a derelict railway waiting-room in some isolated corner of this country, with canine excreta on the floor, and you will be somewhere near it

Finally—and this applies to several of the airlines I have sampled—when the departure of a plane is delayed, why are the passengers not told the reason? Any passenger who tries to obtain such information from the ground staff can be sure of a rebuff, and this is all the more irritating because the full details are always forthcoming from the crew once the plane is in flight Two years ago we were delayed for hours at Gander on our return absurdity of having to increase administrative costs in order to bring down total outlay could be avoided if doctors, dentists, and opticians worked in publicly provided health centres or clinics ”

More fundamental was the basic dilemma of the N H S how with limited resources to meet a potentially unlimited demand for medical care—how to impose a ceiling on “ production ” when the lid was taken off “ consumption ” The service was based on the naïve idea that it was simple to decide what was medically necessary, and that all such needs must be met

> ‘ There are two objections to this view First, there is a large subjective element even in the professional view of what is ‘ medically necessary,’ especially in such matters as buildings, equipment, and ambulance rides If the head of every department of every hospital were to write down his ideal requirements for good work, and all the bills were added up, the present outlay on hospitals might have to be raised three or four times to meet the total Secondly, the subjective element is even stronger in the patient’s mind Medical care tends to reverse normal economic laws the supply tends to create the demand, rather than vice versa The priestly function of the doctor, for instance, is capable of indefinite expansion , so possibly is the cosmetic use of spectacles and dentures, and the use of hospitals as hostels for elderly relatives unwanted at home ”

For checks that were not merely arbitrary two sets of criteria were required (1) standards of quality of professional work, staffing, accommodation, and other aspects of care , and (2) standards of cost of necessary work efficiently performed

The problem of rational financing was made harder by the fatal division between responsibility for the use of resources and responsibility for providing them , this ran right through the N H S but was most marked in the hospitals The Ministry, lacking any sure means of judging how far their requests were reasonable, had yielded to the fatal temptation to control the affairs of the hospitals in detail The bureaucratic control predicted by the opponents of the N H S had in fact been imposed on the hospitals Economy was possible without this , and it even fostered waste

> “ I fail to see how the need for economy justifies these controls By fixing an annual sum not to be exceeded by the hospitals as a whole, the Government has already taken the first step towards making them unnecessary The second step would be to treat this as a pool to be shared among the regions for the time being according to some rough criterion of relative needs, of a necessarily empirical kind The third step would be to leave each regional board free within broad limits to share its funds between its management committees as it chooses the fourth to give the committees a reasonable freedom to manage their own ‘ block budgets including a right to save money without forfeiting it Until the development of hospital costing yields reliable means of measuring efficiency and needs such a system would of course be arbitrary But the present system is not only just as arbitrary it is also bureaucratic and damaging to the whole spirit of the hospital service ’

As to checking the public appetite for health service care, the first need was to examine the professional man’s position, and to remove from his working environment any features tending to deprive him of incentives to economy, or giving him an incentive to be over lenient with his less sensible patients There was too a certain scope for more direct measures, including charges to patients

> Generally, I think there is a case now for introducing charges in the N H S for articles rather than for services, but only in cases where without creating a new financial barrier to necessary care charges would result in a real overall economy There is little point in using charges to reduce the public cost of a service if this merely sends up private spending by an equivalent amount That is I suspect, precisely what would happen if a charge were introduced for board and lodging in hospital ’

Ideally, said Mr Lafitte, the whole N H S budget should be directed to securing the rational deployment of all available medical resources It was arguable, too, that one aim should be to build up the “ front line ” services, so as to screen away from the hospitals and other services at the “ rear ” the greatest possible amount of work

> “ My impression is that such wider issues of strategy are not being sufficiently considered, although the long term fate of medicine in part depends on them, because it is no-one s job outside Whitehall to look at the pattern of needs and resources in medical care as a whole In most places I suspect that they [the hospital authorities] have the most influence in determining the whole pattern and trends of development of the medical care and services The shape they are imposing is, I suspect, derived from their own particular attitude to medical care, which is largely that of the specialist clinicians, and the general trend seems to be for them to claim all the work which interests them and to leave the rest to other agencies If I am right, the budgetary implications may be very great in the long run, since the hospital is the most expensive means of supplying medical care If specialists, general practitioners, and midwives—or ‘ general ’ and priority dentists—were all on the same payroll, is it not likely that developments in many places would be going along different lines ? It may well be that we shall have neither ‘ rational planning ’ nor economical budgeting until the power to allocate funds between the different branches of the N H S is vested in some authority, below the level of central government, which is competent to look at every aspect of the position in a particular place, and is responsible for finding part of the necessary funds from local, not central, sources ”

Planning and Coördination

Dr W G PATTERSON declared that major hospital planning should be considered by the appropriate local health authority, whose observations might be of great value At present there might be no consultation, not because the board was opposed to it, but because the board and its officers were so overworked that they did not go out of their way to initiate time consuming discussions Formal consultation should be obligatory, but, failing this, a suitable liaison committee should be set up As regards cooperation between board and management committee, Dr Patterson had seen great benefit result where the chairman of the management committee was a member of the board At regional board level administrative officers were at present overtaxed , and he believed that the gravest immediate impediment to an efficient service lay in the risk of a breakdown in the administrative medical and architect organisation of regional boards

Another difficulty was the poor general practitioner representation on regional boards , and Dr Patterson was convinced that this accounted in part for some failure in cooperation between boards and practitioners To secure committee member cooperation, on local matters, between the three branches of the service, each hospital region should have several liaison committee including members of local health authorities, local sanitary authorities, executive councils, and hospital management committees , and each liaison committee should preferably cover a population of about 300,000 Officers should also have a local officer liaison committee At regional level there was need for a regional health services liaison committee, including members of the regional board, the board of governors, local health authorities, and executive councils To avoid unwieldy size, local health authorities and executive councils might have to agree to token membership

Observation had convinced Dr Patterson that the best domiciliary general practice was found where practitioners attended patients in a good cottage hospital ‘ Indeed, I hold that where there is no cottage hospital available the large general hospital should include demand for treatment that should follow a nation-wide attempt at breaking down the fear of cancer

London, W C 1 SIDNEY RUSS

TUBERCULOSIS AND OVERCROWDING

SIR,—When our efforts against tuberculosis fall short of what we hope for, we are apt to give a disclamatory shrug of the shoulders and say "Well, after all, it's a social problem, for example, overcrowding is a major factor which we cannot influence" Time invalidates many generalisations and they become clichés obstructing thought and action

Do we really have to wait until the nation is properly housed before overcrowding ceases to be an important factor? Overcrowding in the absence of a case of tuberculosis is not a cause of tuberculosis—it merely facilitates gross infection in the presence of an open case If many cases of tuberculosis are unknown, this effect of overcrowding can only be abolished by the gigantic long term process of rehousing everyone who is living in overcrowded conditions If diagnosis was very efficient and most cases were known, it would only be necessary for tuberculosis control to rehouse the families of the tuberculous cases The overcrowding problem in relation to its effect on tuberculosis would then be almost abolished But a large proportion of cases are *unknown* and so cannot be rehoused

The problem of overcrowding (in relation to tuberculosis) therefore turns out to be a diagnostic one We do not know who should be rehoused because we do not know who has tuberculosis The problem of overcrowding can be overcome by better case finding Of course, it is generally accepted that known tuberculous cases shall be rehoused with priority (which is too low) What is not recognised is that, given rehousing, overcrowding is only a factor in the tuberculosis problem because the *unknown* cases (infection spreaders) cannot be rehoused The need for nation wide serial radiography of those living in overcrowded conditions follows as a corollary to this argument

COMPLICATIONS OF SPINAL ANÆSTHESIA

SIR,—May I be permitted to draw attention to an important omission from your annotation of March 3? Most of the serious sequelæ you listed—such as cauda equina syndrome and impotence—were probably due to the custom of keeping ampoules of local anæsthetics (used for spinal anæsthesia), in spirit or formaldehyde, or mixtures of these two Ampoules kept for long periods in this way may develop minute cracks due to movement of the containers and collisions between ampoules and the container-walls In this event the spirit or formaldehyde, having a low molecular weight, will readily diffuse into the ampoules, and the cases you mentioned were probably caused by the injection of these mixtures into the subarachnoid space

Nicholson and Eversole[1] first drew attention to this complication—mentioning that the cracks were invisible to the naked eye—and suggested the use of "non irritating, *coloured* sterilizing solutions of high molecular weight such as benzalkonium chloride (Zephiran)" The addition of a dye (e g, methylene blue) to the solution in which ampoules are immersed "is of value in detecting the occasional defective ampoule into which the sterilizing solution has leaked Although Kennedy et al.,[2] whose paper prompted your annotation, refer to Nicholson and Eversole they appear to have overlooked the portion of the paper I quote

Stenberg[3] later reaffirmed the usefulness of coloured sterilising solutions, mentioning that he had detected four defective ampoules by this method in a matter of months He also quoted two occasions when local-anæsthetic solutions kept in uncoloured spirit produced small sloughs when used to raise a skin weal prior to lumbar puncture

When using ampoules of dry procaine crystals (which are dissolved in cerebrospinal fluid immediately before injection) we are on safer ground for, should minute cracks allow spirit or formaldehyde to enter the ampoule, the contents would liquefy Macintosh[4] states that he has repeatedly proved such contents to be inflammable

Nowadays most hospitals autoclave the ampoules in the "spinal drum," which also contains rubber gloves, towels, syringes, needles, &c, which are necessary for an aseptic lumbar puncture From conversations with other anæsthetists it is my impression that where these precautions are taken the serious sequelæ of spinal anæsthesia have ceased to occur, I would be interested to know whether this opinion is shared by colleagues elsewhere

VACCINATION AGAINST SMALLPOX

SIR,—For many years Dr Killick Millard has emphasised the difficulty of diagnosing variola major which is modified as a result of vaccination, and this difficulty has been demonstrated again and again at the start of outbreaks in the United Kingdom Dr Millard recommends that, by discouraging vaccination of the general population, as opposed to individuals who are particularly at risk, we should ensure that as many cases as possible of variola major are unmodified and therefore the more easily recognised He replies effectively to one objection of the orthodox vaccinists such as Dr Gemmill (Feb 10) by pointing out that herd immunity in this country has for many years been too low to play much part in preventing the spread of smallpox If this solution fails to take account of mild cases in the unvaccinated, and is regarded as otherwise incorrect and unpalatable, how should the problem be tackled?

To require all persons entering the country to produce evidence of recent vaccination, as advocated by Professor Taylor (March 10), would lessen, but would not end, the risk of variola major being introduced

Whatever else is done the standard of smallpox diagnosis must be improved Dr Rao (March 10) mentions laboratory methods of identifying the virus, but, efficient though these are in a high proportion of cases, neither they nor the help of medical officers of health and smallpox consultants can be used until the disease is suspected clinically Two things are therefore necessary (1) the patient should seek medical advice promptly, and (2) the doctor should include smallpox among the diagnostic pitfalls which he keeps constantly in mind The exacting responsibility which the doctor may have to bear is clear to all readers of THE LANCET, and the rule of regarding all doubtful cases as smallpox until the opposite is proved is indispensable Nor is it possible to be certain that the patient will come under observation before many others have suffered risk, but the standard of public information on this matter could be much improved Some still believe that vaccination prevents smallpox absolutely for at least seven years, few understand how greatly it may modify the attack without stopping the patient from infecting others journey in an American air liner, and the ground staff were so mysterious about it that the more nervous passengers began to wonder whether it would be safer to abandon the flight, and even we phlegmatic ones were reconciling ourselves to an uncomfortable night at the airport. Yet directly we took off the crew told us all about it—there had been some trouble with the undercarriage which the captain had insisted on having repaired before we took off on the long hop to Heath Row. Delays and hold-ups must occur occasionally, but these stony silences do not make them more bearable.

* * *

Through the vestibule of a ward dingy in everything except its eponym I reached the bedside of one of its more decrepit temporary inhabitants. My breezy overtures produced a tale of suffering inconsequent as it was incoherent. Not that my victim was uncoöperative—she was out to help all she could—but match a straight question with a straight answer she could not, though she reiterated the source of her afflictions, consumption contracted in 1917 taking her to and from hospital ever since, with a coronary thrombosis at Christmas, 1950. She was vague about her symptoms, but quite definite about the times when her sputum was positive. When I came to examining her she could not lie straight or draw a decent breath, and she objected vehemently to the clamminess of my nervous hands; but she told me accurately the direction of her tracheal displacement, the site of her apex-beat, and the size of her cavity. She would not tolerate my thumping her knees, but she assured me that no amount of reinforcement would restore her lost reflexes. And her information was offered as amicably as one could wish. So I prepared to meet the examiner with a respectable array of facts and a clear conscience. I had even made an exhaustive though negative urine analysis when a sympathetic registrar led me to the place of execution. Here the softening-up process was taken over by a caricature of a noteworthy examiner whose gimlet eyes and hectoring voice quelled his milder colleagues. “Nought marks, nought marks! Write it down. Nought marks! And I'll add a note to the censors that he must never again take the examination. The fellow got the patient to tell him the diagnosis! I'll not be treated in this way . . .” I did not wait for his peroration. With terror in my heart I dashed for the door. It was barred by white coated registrars. I turned towards a window, burst it open, and jumped, to fall down and down, into pitch darkness.

I did not know where I had landed, but I was shaken, literally physically shaken. And then pinched. “Wake up darling and say nice things to me”—it was my wife's voice—“I've just had a horrid dream that you failed your Membership again . . .”

* * *

Stimulated by the good example of St. Francis I take a bit of trouble about the birds in my garden. I have rigged up a sort of platform on a stake driven into the ground, and each morning I spread upon it the remnants of the dog's dinner. The local robin always gets there first and behaves in a dog-in-the-*salle-à-manger* manner, driving off not only the tits, chaffinches, and sparrows but also the thrushes, blackbirds, and starlings for a long time after he has eaten his fill. By lunch-time all is eaten and the birds are hanging around waiting for their next meal. Now I do not object to feeding the birds during frosty or snowy weather, but when the ground is soft and wet I see no reason why the brutes shouldn't pick up their own living. They, it seems, think otherwise and leave the job entirely to me—just one more example, I suppose, of the enervation of character produced by the Welfare State.

* * *

Believe it or not, but the following is a verbatim extract from a patient's reply to a follow-up letter:

> “I have filled the form up best to my advantage But since my Home Help as had to exspire on account of me having to pay . . .”

Aphorism of the Week

An observant parent's evidence may be disproved but should never be ignored.

Letters to the Editor

PUBLICITY IN CANCER

SIR,—It is timely perhaps to inquire whether a policy of publicity in relation to cancer would serve a useful purpose. If it can be shown that some lives can be saved by this means, then it should be asked of those who oppose the policy, in what ways would harm be done if it were put into practice?

I venture to draw attention to one feature of treatment and suggest that publicity should begin by attempting to drive it home. One of the greatest handicaps to treatment at the present time is the late stage of the disease when cancer patients come to the clinics. It is agreed that the chances of successful treatment diminish gravely as the later stages of the disease appear; if patients could be induced to pay more regard to the early signs of something being wrong, to overcome their scruples about worrying the doctor, and to banish from their minds the idea that the trouble will cure itself, then treatment would carry a greater hope and the mortality figures begin to decline.

Relevant data have, through the courtesy of Dr. Ralston Paterson, been supplied to me by the medical statistics department of the Christie Hospital and Holt Radium Institute, Manchester, which allow one to see the present position in a big clinic. Restricting ourselves at the moment to cancer of the breast and of the cervix uteri we have the following:

		Cases examined	
Site	*Clinical stage*	*1932–33*	*1948*
Breast	I	36	22
	II + III + IV	200	293
Cervix uteri	I	17	17
	II + III + IV	219	390

The data repay study; in some respects they tell a very grim story. Patients suffering from cancer of the breast who came to this clinic in 1932–33 numbered 236, and only 15% of them were in stage I of the disease. Any hope that the year 1948 would show an improvement in this deplorably low percentage has not been realised; in fact, the figure is 7·5%. For the cervix uteri the percentages are even worse—7·8% in 1932–33 and 4·4% in 1948.

These are appalling facts; surely the sign to a woman of a small lump in the breast or an unusual uterine happening is easily recognisable, yet they refuse to give word about it. We may well ask: is this false modesty or is it fear? In either case the attitude should be combated, thus helping to bring down the cancer death rate.

One is tempted to essay an evaluation of what would accrue from a successful effort in publicity relating to early signs of the disease. Let us suppose that as a result of enlightened publicity the proportion of patients at this clinic in the two categories of (*a*) stage I and (*b*) other stages, was reversed; a simple calculation shows that if 1000 patients suffering from cancer of the breast were treated by the same methods (surgical and radiological) as now, there would be 454 alive after five years instead of 213—a saving of 241 *extra* lives out of a total of 1000. Turning to uterine cancer, and assuming that the treatment is radiological, we find that the corresponding numbers would be 630 alive after five years instead of 275—a saving of 355 *extra* lives out of a total of 1000.

In 1948 there were approximately 8000 deaths from cancer of the breast and about 3000 from cancer of the cervix uteri. The *extra* lives that would be saved through early recognition of the disease by the patients themselves is so obviously considerable that one is convinced that it is a duty to take the public into official confidence, to lay the significant facts before them, and to make arrangements now for the increasing

When I wrote that immunisation should be considered here for the whole population in the event of war (rather than reserved for the 10% or so in the Armed Forces) it seemed to me that I was stating an obvious case—and one, furthermore, which committees responsible for advising the Government would have already very fully considered.

London W 1   PATRICK CLARKSON

INTRAVENOUS IRON

Sir,—We would like to thank Dr Klopper for his letter published in your issue of March 3. We would point out, however, that we make no claim regarding the existence of a renal threshold of iron, nor do we stress the significance of the iron lost in the urine. We merely report our findings and suggest that such hypotheses are worth considering in future investigations.

As regards the delayed cases, Dr Klopper appears to have misunderstood us. It is perhaps unfortunate that the two paragraphs relating to delayed cases and hæmodilution were in juxtaposition. The finding of hæmodilution was common to all cases whether the improvement was immediate or delayed, and was not specially related to the delay in response to treatment. The delay appeared to be related more to a protein deficiency than any change in blood-volume. Dr Klopper's hypothesis of the displacement of copper from the protein molecule by iron is also attractive and ingenious, but as yet he has supplied no proof of its occurrence.

We agree with Dr Fench (March 17) that hæmodilution is responsible for many of the mathematical aberrations noted in anæmia of pregnancy, but we are not convinced that it is the only factor of importance. Even allowing for hæmodilution, we find in our cases that the utilisation of iron does not reach the theoretical level. We are of the opinion that more important factors are the storage of iron in early pregnancy and fœtal demands in the last trimester. It is also relevant to point out that the hæmoglobin mass increases considerably in normal pregnancy (by as much as 20% of the total according to Smallwood[1] and 12% per sq. m according to Roscoe and Donaldson[2]). Much of his argument is therefore negatived.

EL TOR VIBRIO IN CHLORAMPHENICOL ESTIMATION

Sir,—The principle of our method for the quantitative estimation of antibiotics is to bring together different dilutions of blood serum or other substances with a micro organism sensitive to the antibiotic, and to note the dilutions in which growth of the organism is inhibited, using the micro method of Goslings.[3]

A strain of El Tor vibrio proved very sensitive to chloramphenicol, its growth being completely inhibited in the presence of 0·5 γ per ml. In tests on fifty sera, we found that inactivating them at 56°C for 30 minutes abolished their natural bactericidal effect, which may otherwise cause a false or "pseudo" titre.

The El Tor vibrio used was isolated twenty years ago from pilgrims in El Tor quarantine camp (Doorenbos) and has kept its capacity to produce active exohæmolysins in liquid media. It grows well in peptone water of pH 7·2 to which 5% defibrinated sheep's blood has been added; after incubation at 37°C for 18 hours the pH of the medium increases to 7·4. The optimum pH for the activity of chloramphenicol being 7·2, the conditions are satisfactory for its quantitative estimation, using hæmolysis as an indicator.

The inhibitory effect of urine on the vibrio can be abolished by keeping it for 15 minutes at 100°C. After adding a known quantity of chloramphenicol—e.g., 5 γ per ml.—to sixty different urines and to seven sputa, we found that heating at 100°C did not affect the quantity of the antibiotic. By rendering the vibrio resistant to penicillin (100 units per ml.) and to streptomycin (100 γ per ml.), it could be used to test the sera of patients undergoing simultaneous treatment with these antibiotics, especially for the presence of chloramphenicol.

Our conclusion is that quantitative estimation of chloramphenicol by the use of El Tor vibrio (Doorenbos) is of practical importance. The strain of El Tor vibrio can be obtained from the laboratory of the Academisch Ziekenhuis, Leiden, or from the National Collection of Type Cultures, Colindale Avenue, London, N W 9.

VERATRUM IN HYPERTENSION

Sir,—Your leading article of March 10 gives an altogether misleading account of what is known of the mode of action of the veratrum alkaloids. The essential difference between these and, for instance, the methonium compounds is that whereas the latter cause a fall of blood-pressure by interfering with the transmission of impulses on the *efferent* side of the cardiovascular reflex systems, the veratrum alkaloids have their principal effect on the circulation by exciting receptors on the *afferent* side of the reflex arc.

As long ago as 1868 von Bezold and Hirt[1] described the fall of blood pressure and heart rate which follows the intravenous injection of crude veratrum preparations and came to the conclusion that this must be due to a reflex action initiated by the stimulation of receptors, probably in the heart itself. Interest in the subject was revived by Jarisch and his colleagues,[2] who confirmed Bezold's original observation that the circulatory response to the intravenous injection of veratrine was abolished by cutting both vagi, and came to similar conclusions as to the location of the receptors. By this time much more was known about the reflex control of the circulation, and Jarisch pointed out that the anatomical and physiological basis for the Bezold reflex had still to be discovered. A few years later Krayer and his colleagues[3] took up the story. They showed that if large doses of the pure alkaloids were used these had a direct action on the central nervous system, but that in considerably smaller doses—and this is most probably the case in man—the whole fall of blood pressure and heart-rate could be explained by the Bezold reflex. The receptors for the reflex are located in the area of distribution of the coronary arteries, probably in the left ventricle.[4] They have not yet been positively identified with any physiological mechanism, though the suggestion has been made[2,5] that they serve the purpose of limiting the pressure rise in the left ventricle. The further elucidation of the Bezold reflex mechanism has therefore considerable physiological interest.

Another feature of the actions of these alkaloids which interested physiologists for many years was the veratrine "contracture," which was eventually traced to excitation of repetitive discharges in muscle and in nerve.[6] The ability of veratrine and of the pure alkaloids to cause repetitive discharges in nerves and stretch receptors[5]

C D L LYCETT

TREATMENT OF SMALLPOX A SUGGESTION

SIR,—Dr Alexander L Hoyne[1] says of confluent smallpox that "with an extensive destruction of the skin the situation is little different with that of a patient who has a burn involving a large area of the skin"

Dr M James Whitelaw[2] has successfully used adrenocorticotropic hormone (A C T H) for burns of the skin, notably in one case where 70% of the skin was destroyed Dr A Benson Cannon et al,[3] using A C T H and 'Cortisone,' have had good results in severe cases of pemphigus vulgaris, one case of pemphigus vegetans, two cases of erythema multiforme pemphigoides, and two cases of epidermolysis bullosa

Is there not a possibility that cases of smallpox might be treated successfully with A C T H in early stages of the disease or even in severe cases after skin destruction? It is impossible to make the experiment in the United States at present, since fortunately we have not enough cases, and those few we have are widely scattered

Smallpox is epidemic in India and China, where your journal goes If the experiment has been made, it has not come to my attention

ARTHUR S BRACKETT

PENICILLIN IN WEIL'S DISEASE

SIR,—Since the publication of my paper in your issue of Jan 13, my attention has been drawn to an article written in 1949 by Lurie,[4] describing the use of 'Aureomycin' in a case of leptospirosis icterohæmorrhagica

An agricultural worker, aged 32, was admitted to hospital with all the classical signs of Weil's disease, confirmed on the fourth day after admission by a strongly positive agglutination test From the degree of hepatic and renal involvement it appears that this was a rather severe case of leptospirosis The patient was treated with aureomycin 2 g daily for the first three days, and thereafter 1 g daily for eleven days The response to aureomycin treatment was immediate and the patient recovered completely He was in hospital for twenty three days and on discharge blood urea, serum bilirubin, and urine were normal

In 1949 Brainerd et al[5] reported the use of aureomycin in one case of Weil's disease

A sewer worker was admitted to hospital unconscious and jaundiced, with nephritis and evidence of subarachnoid bleeding Leptospira were demonstrated on two consecutive days by dark field examination of blood Aureomycin was given in 1 g doses orally every six hours for twelve days, in addition, 100 mg of the drug was injected intravenously three times a day during the first five days Improvement was rapid The icteric index, originally 125, fell to 17 in about a week, and the blood urea from 120 mg per 100 ml to 21 mg per 100 ml in five days The patient made a full recovery, and the authors have this to say "Although the rapid improvement could not certainly be attributed to aureomycin, it was felt that specific anti spirochætal effect was most likely"

Another interesting case was reported by Batchelor and Todd[6] in 1950 They used aureomycin after penicillin had failed to halt the progression of toxæmia

The patient was a negro admitted to hospital with high fever hepatorenal syndrome, and subarachnoid bleeding When the diagnosis of Weil's disease was ascertained, treatment was started with 600,000 units of procaine penicillin in oil four times daily and 200,000 units of sodium penicillin intramuscularly every two hours After thirty six hours the patient became moribund Aureomycin was then started, an initial dose of 2 g was given, followed by 250 mg every three hours Twelve hours after starting aureomycin the patient improved sufficiently to take sips of water The dosage was then increased to 500 mg three hourly and was continued until 17 25 g had been given Convalescence started on the fifth day after admission It is to be noted, however, that penicillin was continued throughout the aureomycin therapy This makes it difficult to say which of the two antibiotics was the life saving drug

Lurie's and Brainerd's cases of Weil's disease were probably the first two on record to have been treated with aureomycin, and no doubt since 1949 many more patients with leptospirosis have been treated successfully with this antibiotic, thus confirming clinically the therapeutic results obtained by Heilman[7] in experimental leptospiral infection

PROPHYLAXIS AGAINST TETANUS IN BURNS

SIR,—Dr Colebrook (March 10) raises an important question about which opinion is divided Some believe that the risk of tetanus in burns is negligible, others consider it sufficient to warrant routine prophylaxis for all burned patients

May I first answer Dr Colebrook's questions? My own experience in burn patients is less than his (it comprises two thousand cases treated during the last ten years in Africa, Italy, Europe, and England), but I have seen tetanus in three patients, one of them with a trivial burn, and know of its occurrence in four other burned patients during this period All seven of these patients were burned in the south west of England or in East Anglia (This is not surprising in the light of Conybeare and Logan's paper,[8] which draws attention to the fact that tetanus from all causes in civil life in England is most common in the South west and East) These were no cases in the burns seen outside England There were soldiers who had had both toxoid and anti tetanus serum injections

None of these seven cases has been published But as Dr Colebrook will of course be aware, tetanus as a complication in burns is reviewed in Harkins's textbook *Treatment of Burns*, references to over a hundred cases of tetanus following burns are given, including the one to Dupuytren which I mentioned in my review (Feb 24) on account of its historical interest

Although the complication is undoubtedly rare, I agree with those who believe that it is not so rare in civil life that it can be ignored The chance of tetanus is unpredictable, the nature of the disease and its still high mortality outweigh, in my view, the cost of prophylaxis and the undoubted disadvantages of serum sickness

In my general account of the management of burns, to which Dr Colebrook refers, I made it clear that my remarks were directed towards burns in any future war, with special reference to the effects of atomic explosions, in which lacerating injuries may be expected to be as common as burns Conybeare and Logan consider the risk of tetanus sufficiently high in peace time injuries to warrant consideration of active immunisation of the population in certain regions of England Truman Blocker at the Washington symposium on burns[9] expressed the opinion "that it is imperative that mass immunisation of our whole population be carried out"

London, W 1

INTRAVENOUS IRON

SIR,—We would like to thank Dr Klopper for his letter published in your issue of March 3 We would point out, however, that we make no claim regarding the existence of a renal threshold of iron, nor do we stress the significance of the iron lost in the urine We merely report our findings and suggest that such hypotheses are worth considering in future investigations

As regards the delayed cases, Dr Klopper appears to have misunderstood us It is perhaps unfortunate that the two paragraphs relating to delayed cases and hæmodilution were in juxtaposition The finding of hæmodilution was common to all cases whether the improvement was immediate or delayed, and was not specially related to the delay in response to treatment The delay appeared to be related more to a protein deficiency than any change in blood-volume Dr Klopper's hypothesis of the displacement of copper from the protein molecule by iron is also attractive and ingenious, but as yet he has supplied no proof of its occurrence

We agree with Dr Fench (March 17) that hæmodilution is responsible for many of the mathematical aberrations noted in anæmia of pregnancy, but we are not convinced that it is the only factor of importance. Even allowing for hæmodilution, we find in our cases that the utilisation of iron does not reach the theoretical level We are of the opinion that more important factors are the storage of iron in early pregnancy and fœtal demands in the last trimester It is also relevant to point out that the hæmoglobin mass increases considerably in normal pregnancy (by as much as 20% of the total according to Smallwood,[1] and 12% per sq in according to Roscoe and Donaldson [2]) Much of his argument is therefore negatived

EL TOR VIBRIO IN CHLORAMPHENICOL ESTIMATION

SIR,—The principle of our method for the quantitative estimation of antibiotics is to bring together different dilutions of blood serum or other substances with a micro organism sensitive to the antibiotic, and to note the dilutions in which growth of the organism is inhibited, using the micro method of Goslings [3]

A strain of El Tor vibrio proved very sensitive to chloramphenicol, its growth being completely inhibited in the presence of 0 5 γ per ml. In tests on fifty sera, we found that inactivating them at 56°C for 30 minutes abolished their natural bactericidal effect which may otherwise cause a false or "pseudo" titre

The El Tor vibrio used was isolated twenty years ago from pilgrims in El Tor quarantine camp (Doorenbos) and has kept its capacity to produce active exohæmolysins in liquid media It grows well in peptone water of pH 7 2 to which 5% defibrinated sheep's blood has been added, after incubation at 37°C for 18 hours the pH of the medium increases to 7 4 The optimum pH for the activity of chloramphenicol being 7 2, the conditions are satisfactory for its quantitative estimation, using hæmolysis as an indicator

The inhibitory effect of urine on the vibrio can be abolished by keeping it for 15 minutes at 100°C After adding a known quantity of chloramphenicol—e g, 5 γ per ml—to sixty different urines and to seven sputa, we found that heating at 100°C did not affect the quantity of the antibiotic By rendering the vibrio resistant to penicillin (100 units per ml) and to streptomycin (100 γ per ml), it could be used to test the sera of patients undergoing simultaneous treatment with these antibiotics, especially for the presence of chloramphenicol

Our conclusion is that quantitative estimation of chloramphenicol by the use of El Tor vibrio (Doorenbos) is of practical importance. The strain of El Tor vibrio can be obtained from the laboratory of the Academisch Ziekenhuis, Leiden, or from the National Collection of Type Cultures, Colindale Avenue, London, N W 9

The various pure alkaloids differ considerably in their activity and duration of action in causing a fall of blood pressure, which all authors are agreed is due to peripheral vasodilatation It is difficult to see why the immediate mechanism of this vasodilatation should cause such controversy Like other reflex depressor responses it is almost certainly due to a coordinated change in both sympathetic and parasympathetic systems Thus the administration of atropine abolishes the bradycardia but not the decrease in peripheral vascular sympathetic tone, and hence not the fall in blood-pressure These features of the action of the veratrum alkaloids should be of great interest to the clinician, since the fall of blood pressure and heart rate is produced reflexly one would not expect the general circulatory adaptations—the "cold pressor" rise for instance—to be interfered with, and that indeed has been the experience in man [10] For this reason it has always been expected that these alkaloids would have certain advantages over other methods of reducing the blood pressure in hypertensive patients On the other hand, toxic symptoms would also be anticipated from the ubiquity of their actions on muscle and nerve

This ubiquity and the difficulties of tachyphylaxis have hindered progress in unravelling the complicated actions of the veratrum alkaloids in the whole animal How much more difficult is this process in man? There does indeed seem very little hope of obtaining *direct* evidence for the reflex actions of these substances in man, unless it becomes practicable to block the afferent path of the reflex—the cervical vagus nerves—for a short while As an experimental procedure this is hardly justifiable On the other hand, the overwhelming weight of the experimental evidence in animals is in favour of the reflex mode of action with those alkaloids which do cause a profound fall of blood pressure The one exception is the claim by Stutzman and Kusserow,[11] working with a new impure extract of veratrum viride named 'Veriloid' (which Kauntze and Trounce used for their investigations described on March 10), that veriloid causes a fall in blood pressure despite vagotomy It will be interesting to see if these extracts contain alkaloids of such strikingly different properties from the pure substances already investigated It is true that not all veratrum alkaloids, but only some of the ester alkaloids, are capable of producing the reflex fall in blood pressure and heart rate But the inactive alkamines are also virtually inactive upon the circulation Cevine, for instance, lacks the characteristic depressor property in a dose 2000 times the minimal effective dose of its ester alkaloid veratridine And in any case, for the reasons given above, the use of substances which produce a fall of blood pressure by a reflex mechanism would seem to be preferable for clinical purposes

G S DAWES

SLIMMING BY TELEVISION

SIR,—We have for some time been concerned by the publication of dietary advice in the daily press Recently, however, this dissemination of gratuitous information has taken the form of a series of television programmes culminating in the free distribution of obesity diet sheets to any members of the public who cared to apply to the B B C for them

This reducing diet, which is fairly strict, provides 1000 calories a day It has been carefully constructed, and applicants are told to follow it under the guidance of their medical advisers We feel, however, that this injunction will often be disregarded and that many of the 35,000 people already clamouring for diet sheets will endeavour to follow the instructions without recourse to their doctors

It has always been a principle of our profession that no dietary advice should be given without specific instructions from the patient's doctor No printed diet sheet should ever be handed out, moreover, without an interview during which the dietitian satisfies herself that the patient has understood the principles of the régime, that it is within his means, and that it is suited to the social conditions under which he lives She will also arrange for the patient to be kept under supervision so that she can assure herself that the diet is proving suitable, that it has been understood, and that it is being applied

None of these conditions is entirely fulfilled by the present large scale distribution of diet sheets We feel that this situation is undesirable and even potentially dangerous

CHRONIC NON-TUBERCULOUS ABSCESS AT SITE OF INJECTIONS

SIR,—I was interested in the paper of March 10 by Dr Fielding and Dr Norris, describing the unusually large number of abscesses seen by them in patients who had received penicillin injections They report that most of these were sterile on culture, and the clinical and pathological features, which they carefully studied, suggested the presence of a common irritant

Amongst the first 17 cases seen by me and treated with 'Cortisone' from different batches, no less than 5 large abscesses developed Of these 2 were opened by surgeons of repute, but seemed to heal unusually slowly, indeed one of these is still discharging slightly more than six months after operation The other 3 ultimately subsided completely as the result of repeated aspirations Cultures from 2 of these abscesses were reported to contain *Staphylococcus aureus*, but the other 3 were reported as sterile

These abscesses developed very slowly but gave rise to considerable pain and disability They appeared to be situated in the deep subcutaneous fatty tissue, and not intramuscularly I find from conversation with both British and French colleagues that my experience is not unusual, so it seems strange that we seem to have had no reports of this rather troublesome side effect from America, where cortisone originated and has been so much more extensively used

Apart from abscesses, tender indurations in the deep subcutaneous tissues, which are presumably of a similar nature, are not uncommon and would seem to be the result of local irritation, possibly of chemical origin I have seen these also—but never an abscess—as the sequel of A C T H administration Although structurally these two substances are in pure form very different, it may be that they sometimes contain impurities of similar type, and it is the employment of a larger bulk of cortisone than of A C T H which determines actual abscess formation

The therapeutic moral would appear to be that where intramuscular injections of cortisone or A C T H are necessary, great care should be taken to ensure that the substance actually reaches the muscular layer, and is not discharged into the deep subcutaneous tissues In obese patients this will often necessitate the use of a longer needle than is normally employed

W S C COPEMAN

London W 1

RHESUS NOMENCLATURE

SIR,—An article by Renton and Stratton[1] starts "The following notation is used, for the sake of simplicity, in this paper $R_1 = CDe$, $R_o = cDe$, $R' = Cde$, &c" In the same journal Lawler et al[2] use the following "short" symbols rr for cde/cde, R_or for cDe/cde, $R_o R_o$ for cDe/cDe, &c These abbreviations are manifestly minor variations of Wiener's Rh-Hr nomenclature These investigators, therefore, are using two nomenclatures and resort to the Rh Hr nomenclature when it would otherwise be difficult to express themselves clearly The question arises why the British investigators continue to use C D E notations at all The original Rh-Hr notations, aside from having priority, are simple and unambiguous, and certainly one nomenclature is simpler than two

The chief criticism levelled by Race against Wiener's nomenclature is that the symbols are not sufficiently explicit—that is, that the symbols for the agglutinogens do not indicate all of the factors present in the agglutinogen Race[3] has prepared a table (table I) which details this objection The fallacy in Race's criticism is that the purpose of a symbol is to identify, and not to describe in full As a matter of fact, the more fully a symbol becomes descriptive the more unwieldy it becomes For example, in the diagram below are given the properties of the agglutinogens A_1 and A_2

Agglutinogen	*Reaction with anti A*	*Reaction with anti A_1*	*Reaction with anti O*
A_1	+	+	−
A_2	+	−	+

Since the fact that the designations A_1 and A_2 do not indicate the two principal partial antigens which each of the agglutinogens contain causes no difficulty to workers in the field, there is no reason why the symbols Rh_1 and Rh_2 should cause difficulty The fact is that they do not

On the other hand, to attempt to include all that is known about a subject in the symbols may lead to difficulties Firstly, it becomes necessary to change the symbols each time a new antiserum is discovered and as one's concept of the nature of the agglutinogen changes Secondly, when adhering unswervingly to the original preconceived ideas there develops a tendency to force the facts so that they conform to the nomenclature For example, in the article by Lawler et al there appeared the following two sentences "Antigens *C* and *c* are inherited as Mendelian characters and so are *E* and *e*, and *D* and *d* The antigens are inherited in threes, either *C* or *c*, and *D* or *d*, and *E* or *e*" In the first sentence the authors actually can make no statement in regard to the inheritance of *d* because they made no tests in any of their studies using anti-*d* serum The only documented report on *d* is the one by Haberman et al.,[4] and this has been challenged by Wiener[5] because he was unable to confirm their findings with samples of the patient's serum which were sent to him At any rate, if *d* does exist it seems strange that workers like Race, Mourant, Mollison, Levine, Simmons, Bessis, Diamond, and Wiener who have together tested many thousands of human sera containing abnormal antibodies, have been unable to obtain a reagent for this blood property, while so many other new properties recently announced have been immediately confirmed and reagents for them found In view of these considerations any nomenclature that includes a symbol for *d* or Hr_o is misleading and therefore incorrect The second statement is also erroneous because the number of blood factors in an agglutinogen is not uniformly three but may vary between one and four, as table II shows.

TABLE I—RACE'S CRITIQUE OF THE Rh Hr NOMENCLATURE

Nomenclature		Criticism
Fisher	Wiener	
CDe	Rh_1 or $Rh_0 \begin{matrix} \leftarrow = C \\ \leftarrow = D \end{matrix}$	*e* ignored
cDE	Rh_2 or $Rh_0 \begin{matrix} \leftarrow = E \\ \leftarrow = D \end{matrix}$	c ignored
cDe	$Rh_0 \leftarrow = D$	c and *e* ignored
cde	$rh \leftarrow ?\ d$	c and *e* ignored
Cde	$rh \begin{matrix} \leftarrow = C \\ \leftarrow ?\ d \end{matrix}$	*e* ignored
cdE	$rh'' \begin{matrix} \leftarrow = E \\ \leftarrow ?\ d \end{matrix}$	c ignored

The main objection to the C D-E notations is that they are based on a genetic theory that would allow for crossing over For this there is no support whatever, while there are ample data to support Wiener's theory of multiple alleles In fact, the paper by Lawler et al provides additional data supporting the theory of multiple alleles, and as the authors state in their conclusions, "No examples of crossing over have been found in the families tested in this unit, nor do we know of any certain examples found elsewhere The work

TABLE II—BLOOD FACTORS PRESENT IN THE Rh AGGLUTINOGENS

Wiener notations		Reaction with antisera						Fisher-Race notations	
Gene	Corresponding agglutinogen	rh C	rh^w C^w	rh″ E	Rh_0 D	hr c	hr″ e	Designation*	Error
r	rh	−	−	−	−	+	+	*cde*	*d* not demonstrated
r	rh	+	−	−	−	−	+	*Cde*	*d* not demonstrated
r″	rh^y	−	−	+	−	+	−	*cdE*	*d* not demonstrated
r′	rh^y	+	−	+	−	−	−	*CdE*	*d* not demonstrated
R^0	Rh_0	−	−	−	+	+	+	*cDe*	None
R^1	Rh_1	+	−	−	+	−	+	*CDe*	None
R^{1w}	Rh_1^w	+	+	−	+	−	+	C^wDe	*C* omitted four factors present
R^2	Rh_2	−	−	+	+	+	−	*cDE*	None
R^z	Rh_z	+	−	+	+	−	−	*CDE*	None
R^{1y}	Rh_1^y	+	−	−	+	+	−	c^rDe	Symbol does not indicate presence of *C* and *c*†
New rare agglutinogen of Race and Sanger		−	−	−	+	−	−	*–D–*	Contains only one factor

* The Fisher Race nomenclature does not distinguish between genes (chromosomes) and agglutinogens, nor between genotypes and phenotypes.

† Moreover this contradicts the Fisher-Race theory which precludes the presence of both *C* and *c* in the same chromosome and agglutinogen

Brooklyn, New York. IRVING B WEXLER.

CORONARY DISEASE AND MODERN STRESS

SIR,—In manual workers mental activity is accompanied by bodily activity, and while the systolic pressure is raised the heart is well filled by the action of the muscles and valves in the veins and by the increased respiratory pumping action Thus the diastolic supply to the coronary vessels is maintained Mental activity, particularly with anxiety or stress of work in the sedentary professions, excites a rise of systolic pressure which, unaccompanied by muscular activity, does not produce that same maintenance of diastolic pressure which is needed for a good supply of blood to the heart by the coronary arteries This, I suggest, accounts for the far greater prevalence of angina pectoris and coronary thrombosis in busy mental workers than in manual workers To compensate for sedentary mental work I think the *Exercises in the Bath* worked out by Mr T R Togna[1] are of considerable value These exercises do not raise the systolic pressure and they increase the pulse rate very little, but they secure a good return of blood to the heart and high oxygen use per pulse beat Patients with angina have used the exercises with success

Corton near Lowestoft LEONARD HILL

SIR,—May I offer a brief contribution to the problem of coronary disease in physicians and surgeons, mentioned by Dr Rentoul (March 10) and Dr Stewart (Dec 23)

Dunbar has drawn our attention to the factor of exposure The impression from observing heart disease and death from it is, according to her, an important stress agent in patients with relatives and close friends who have suffered from such disease Dunbar concludes from her considerable material that heredity acts only in conjunction with this psychological factor I have been for a long time occupied with the related problem of medical men who suppress the ordinary emotional reactions to the many illnesses they encounter Habit does not wholly eliminate anxiety responses, and these recurrent experiences together with responsibility for the patients may be a potent substitute for the close relationship referred to by Dunbar

London, W 1 S LOWY

WILL WE NEVER LEARN?

SIR,—The subject of this provoking correspondence has always interested me, and I have worked out the mortality rates for gastrectomy at two provincial hospitals where I have been a registrar To continue with Mr MacLellan's metaphor (Feb 3), the pitches were not like Lord's (I have been a registrar spectator there too) but good county grounds nevertheless The mortality-rate for both hospitals combined over a period of three years (132 cases, 7 surgeons) was 13 5% Your correspondents must agree that this is pretty fast bowling A few bowled "slows" (gastro enterostomy), and there were one or two googlies (vagotomies), these had a much lower bowling average

The point I wish to emphasise is that the cause of this poor bowling average was not, in my estimation, that the bowlers were bad, but that they were rushed They bowled 8 ball overs in the time that a professional at Lord's would take to roll up his sleeve I am not referring necessarily to operating time but to time for investigation and preparation—time to think Far more important than the "have a go" mentality (Dr Brailsford, March 10) is the "what's the next case" attitude and the glance at the list and the theatre clock

Orthodox and better bowling will be achieved by improving the pitch, but this will take a long time as we all know An immediate partial solution to Sir Heneage's problem (March 3) lies, not in edicts, a full time service, and control, but in more bowlers The bowlers are there, twice the age of Tattersall, fully trained, waiting I would hazard a guess that the mortality for gastrectomy performed by senior surgical registrars is below the average for the country's consultants They are more careful—they have to be The trouble is that the present bowlers do not want any additions to the team—there will be fewer benefits, and the bonuses will become more infrequent Nor do the county committees wish to increase their staff, for financial reasons

Will Sir Heneage have the courage of the M C C and urge that more bowlers are sent out?

F R.C.S

HEPATITIS FROM TATTOOING

SIR,—The letter from Dr Robertson in your issue of Jan 6 adds still more support to the suggestion that jaundice may be transmitted by inoculation during tattooing Dr H Still and I have described[1] four cases of jaundice which we thought were very probably acquired in this way

Our four patients all attended a certain tattooing den on Feb 5, 1949, and were tattooed in succession Each developed jaundice between June 17 and 29 the same year There was no infectious hepatitis prevalent at the time, and after full inquiry we could not resist the conclusion that the virus of serum hepatitis had been inoculated through the agency of the tattooing needle Dr Ballard F Smith had presumably not seen our article when he presented his paper,[2] but his conclusions were very similar to ours

Since our cases occurred we have made careful inquiries of all our jaundice patients, but have not again demonstrated this causal connection There can be little doubt, however, that there is a real danger of virus transmission during tattooing as usually performed, and stricter control over "artists" is long overdue

Halifax, Nova Scotia R HOWELL ROBERTS

NURSING INFECTIOUS DISEASES

SIR,—The belief that there is no longer a case for fever hospitals, which is widely held and is expressed by Mr Crabb in his letter of March 10, is one of the main obstacles to the recruitment of nurses for these hospitals The would-be nurse is advised that fever nursing is a thing of the past This view has been strengthened by the publication of a proposal to abolish the special certificate in fever nursing Thus, the high standard of nursing and nurse training which fever hospitals maintained is being undermined Yet the demand for their services, as the Emergency Bed Service could testify, remains greater than the fever hospitals at present functioning can satisfy

Despite Mr Crabb's final remark, general hospitals have very little accommodation suitable for infectious cases The extensive reconstruction needed to increase such accommodation is not likely to be undertaken for many years to come The general hospitals realise this, and not only refuse to admit patients suffering from many of the common infections but are anxious to transfer patients who develop such infections while in hospital Meanwhile, those who decry the value or necessity of fever hospitals bear a considerable part of the responsibility for the grave nursing position described by Dr Banks (Feb 3) and Dr Kennedy (Jan 20)

Parliament

Half-closed Shop

ON March 13 on the adjournment Miss FLORENCE HORSBRUGH moved a resolution regretting

> the decision of the Durham County Council in insisting on membership of an appropriate professional association or trade union as a condition of employment.

The council had passed this decision, she recalled, on Nov 1 On Nov 15, when Dr Charles Hill had raised the matter in the House the parliamentary secretary to the Ministry of Health, replying for the Government, had said, "We regret the resolution passed by the Durham County Council." Letters had been sent from the Ministries of Health and Education to the council saying that the Government did not approve of coercion. The council replied that the resolution had been reaffirmed Consultations had then taken place between the Ministries and representatives of the council. The dismissals were not enforced on the appointed day, but the resolution had not yet been rescinded The *Schoolmaster*, the official organ of the National Union of Teachers, had stated that the council's policy was being implemented in another way When candidates were called for an interview they were asked whether they were members of a trade union Miss Horsbrugh cited one instance when five candidates for a headmastership had not answered the question, saying that they had been advised by their union not to do so The sixth candidate had answered and he had got the job

Mr W R. BLYTON moved an amendment, that the House

> while approving the attitude already adopted by His Majesty's Government, and being anxious not to interfere with the autonomy of local authorities, hopes that the discussions now proceeding between the Durham County Council and some of the associations concerned will lead to an amicable settlement of the points at issue.

He had been a staunch trade unionist all his life, and he preferred to describe the situation not as a closed shop but as an attempt to get a 100% trade-union membership He believed, however, that the job of the Durham County Council was that of administrators and not trade-union organisers. Action to force people into unions should come from the bottom and not from the top, and he therefore approved of the Government's attitude The Durham County Council had decided not to implement the disputed resolution, and he could not himself see it was a crime to ask a person if he was a member of a trade union.

Mr GEORGE TOMLINSON, Minister of Education, said he had made it clear to the council that though he approved of teachers joining a union or professional association he did not consider they should be coerced by the action of their employing authority The council had in fact not implemented the resolution they had passed, but it was said that did not matter because the resolution was still on the books. But there were thousands of resolutions still on the books of local authorities and nobody bothered about them It was the action taken of which we must take cognisance. He did not want to interfere with a local authority as to the way it carried out its duties. But unless the N U T and the Durham County Council could be got to come together circumstances might arise in which he would be compelled to issue a direction He did not know whether that might not be just a victory for pigheadedness at the expense of the children.

Dr CHARLES HILL said that whatever force the arguments put forward on grounds of convenience or practical difficulty might have had in the past, it was fundamentally wrong that any man should be compelled to join any organisation of any kind Where an important freedom was involved—whether in the field of religion or whether as a conscientious objection to military service—it was right that the majority should respect the minority Speaking as one who until some months ago was involved in collective bargaining on behalf of a not unimportant body, he believed, there was nothing that kept an organisation on its toes more than the right of members to resign. Again a good trade union might want the right to expel the unsuitable and unwanted member. Must that action carry loss of a man's livelihood? Asking candidates whether they belonged to a union was in principle the same as sacking an existing staff and asking them as a condition of re-employment to produce evidence of trade-union membership Before the House approved of the Government's attitude they should be told what it was The amendment was carried by 298 votes to 283

Tuberculosis a Prescribed Disease

In the House of Commons on March 14 Mr IAIN MACLEOD moved the annulment of the regulation prescribing tuberculosis as an industrial disease for nurses and other health workers[1] Before prescribing a disease the Minister must be satisfied that the disease ought to be treated as a risk of occupation, and that it can be presumed with reasonable certainty to be due to employment. Mr MacLeod questioned whether these conditions had been fulfilled. He also urged that regulations suggesting, as they did, that nurses had an additional chance of contracting tuberculosis by reason of their employment might adversely affect the recruitment of nurses On what evidence had these regulations been made? The Advisory Council, whose recommendations had presumably been accepted by the Minister, had said that few statistics were available What statistics there were, notably those contained in the report on the Prophit Tuberculosis Survey, indicated a higher incidence of tuberculosis in nurses in general hospitals than in nurses in sanatoria. Tuberculosis, Mr MacLeod pointed out, was being prescribed because it was a communicable disease Did not all other communicable diseases immediately come into consideration? Nurses in infectious diseases hospitals, for instance, had an additional risk. The Trades Union Congress had stated that in their opinion every disease which could be shown to be contracted by virtue of employment should be prescribed, and that view was supported independently by the Royal College of Physicians Mr MacLeod was sympathetic to this point of view, but it was, he said, the end of the Industrial Injuries conception as they had known it since 1897 Mr MacLeod said he did not propose to press the motion to a division, but he had thought it right to submit to the House the case against the regulations

Dr H B MORGAN said that the Trades Union Congress had been concerned with this matter for years. They had gone through it with a fine comb and they were perfectly satisfied that at present these regulations went as far as it was legitimately possible to go in protecting the interests of workers exposed to tuberculosis infection

Mr C J ALPORT asked what was the position of a wife looking after her husband. Could her husband employ her as an attendant? Were medical students also included in the definition of the schedule?

Mr BERNARD TAYLOR, parliamentary secretary to the Ministry of National Insurance, said he did not share the gloom or pessimism of those who opposed the regulations So far from being apologetic about them, the Government were proud to have had an opportunity of introducing them and were convinced that they would prove of benefit to nurses and others who came into contact with tuberculosis patients In the view of the Minister of National Insurance the report of the Advisory Council contained abundant evidence of an added risk among the nurses in the occupations mentioned. Even if there were only one case he claimed that that would be a complete justification for the regulations The sort of men and women who entered the nursing profession were not likely to be deterred by the knowledge that there may be certain risks attached The Government were satisfied that only those who were really at some special risk would be able to qualify for benefit The regulations were intended to cover ward maids, hospital laundry workers and tuberculosis visitors, but the occupation must be insurable under the Industrial Injuries Act The Ministry had arranged with the coöperation of the Health Departments that on every claim under the new regulations they would have specialist advice

Royal Commission on Divorce

Replying to a number of questions the Prime Minister announced on March 14 that he had decided to recommend the appointment of a Royal Commission to review

---

AN EVALUATION OF PUBLIC-HEALTH MEASURES FOR THE CONTROL OF SYPHILIS

AN EPIDEMIOLOGICAL STUDY*

JOSEPH EARLE MOORE
M.D. Johns Hopkins

From the Venereal Disease Division of the Medical Clinic Johns Hopkins University and Hospital, Baltimore

SYPHILIS control in the modern sense, dates from 1905–10, and the fundamental discoveries of Schaudinn (*Treponema pallidum*), Wassermann, Neisser, and Bruck (a diagnostic test), and Ehrlich ('Salvarsan'). Before 1910, and for lack of these basic scientific discoveries little or nothing could be, or was, done.

In the intervening 40 years, all civilised countries have recognised the danger to public health and welfare imposed by syphilis, and each has engaged in programmes, comprehensive or partial, looking toward its control and, hopefully, to its eventual eradication. Leadership in the development and application of such programmes was taken first in Scandinavia, and more recently, within the last 15 years, in the United States.

Stimulated by recent advances in knowledge, many public-health administrators view the future with extreme optimism. They believe that the application of existing knowledge will effect control of this disease and perhaps eventual eradication. It is proposed here to review past experience, with a view to determining whether this optimism is well founded. To this end it is pertinent to examine (1) available data which reflect incidence of syphilis in human populations in the years prior to 1910, before scientific measures of control were applied; (2) the principal factors which determine fluctuations in incidence and its trend during this period; (3) the extent to which these factors are still operative in the modern period since 1910; and (4) the additional effect of measures represented by advances in knowledge in the modern period.

The geographical areas and the time periods for which morbidity and mortality rates from syphilis are available are extremely limited. Moreover, completely accurate information as to morbidity and mortality of the group of venereal diseases is prevented by the social implications of their method of transmission, and, in the case of syphilis at least, by its biological, often nearly symptomless, course. Legal requirements as to reporting morbidity and mortality to the health authorities have differed widely in various countries, in different parts of the same country, or from time to time within a particular community. Epidemiological data are often confused by consolidation of the entire group of diseases because of their common mode of transmission, and without regard to separate infectious entities. The trend of "venereal disease" incidence does not necessarily express the trend of incidence of a particular infection, since the rate of one may remain stationary, or even rise, while the rate of another falls—e.g., gonorrhœa as compared with syphilis.

The Public-health Implications of Early versus Late Syphilis

For practical epidemiological purposes, syphilis is not one but two diseases. One of these, early syphilis (i.e., the first 2 to 4 years), represents an acute infection. Infectiousness is concentrated largely within the first year, diminishing rapidly thereafter so that by the end of the fourth year the risk of transmission from one adult to another has almost, if not entirely, disappeared. The other, late syphilis (i.e., of more than 4 years' duration), is a public-health problem comparable in importance to such non-infectious conditions as hypertension and cancer.

It is necessary at the outset to distinguish clearly between the epidemiological terms "incidence" and "prevalence." An attack upon early syphilis should be calculated to break the chain of infectiousness, thereby reducing the *incidence* of fresh infections, and ultimately, within a generation or more, to reduce also the reservoir (i.e., *prevalence*) of late syphilis. In the following discussion, major interest lies in incidence—the rate and extent of dissemination of syphilitic infection.

The public-health objective may be clearly stated by changing only three words in the remarks of Frost (1937) on the control of tuberculosis:

> "It is not necessary that transmission be *immediately* and *completely* prevented. [Italics are Frost's.] It is necessary only that the rate of transmission be held permanently below the level at which a given number of infection spreading (i.e., 'open') cases succeed in establishing an equivalent number (of 'open' cases) to carry on the succession. If, in successive periods of time the number of infectious hosts is continuously reduced, the end result of this diminishing ratio if continued long enough must be extermination of the *treponeme of syphilis*. [Italicised words are the three I have substituted.]

Unavoidably, however, a public-health attack is simultaneously directed at late syphilis as well—here without major influence upon incidence (in the epidemiological sense), but instead for the purpose of preventing or treating late complications and thereby minimising invalidism, death, and community cost.

This elementary epidemiological recognition of the division of syphilis into two separate entities has been laggard in application to public-health practice. Where incidence and prevalence data have been collected, it has been customary to record all syphilis as a group, without distinction between its two epidemiological types. In England and Wales, for example, figures as to incidence of early syphilis as such are available only since 1932; in the United States as a whole, only since 1941.

There are exceptions to this epidemiological confusion in various countries and in certain small populations, notably military rather than civilian, though the entanglement is so serious as to give the epidemiologist pause in evaluating long-term trends.

EARLY DATA AS TO MORBIDITY AND MORTALITY

In civilian as opposed to military populations, there is therefore singularly little information as to trend of incidence of syphilis until very recent years. It is known (Hirsch 1885, Bloch 1901), without statistical documentation, that the infection spread in major epidemic fashion over Western Europe in the late 15th and early 16th centuries, and thereafter over the entire world; and that from time to time since there have been minor epidemics or major endemics (Scotland, mid-17th century; Scandinavia, early 18th century; Serbia, early 19th century).

It is also established, on reliable clinical testimony, though again without statistical proof, that the characteristics of the disease have undergone a profound change in the 450 years of its recognised history. An often rapidly fatal infection has evolved into one of exquisite chronicity. Malignant, destructive lesions of the skin, mucosæ and bones have been replaced by less obvious but more serious cardiovascular or nervous system involvement, or even by almost complete clinical latency. There is indeed some evidence of a change in clinical character in the United States within the last thirty years. The incidence of early asymptomatic neurosyphilis'

GRAHAM STEWART—BISHOP—On March 14 at Nettleden Herts Colin Woodward Graham Stewart F R C S, to Gillian Mary Bishop

DEATHS

AVENT—On March 13 at Seaton, Devon Arthur Avent L.R.C.P E
SMITH—On March 12, in Edinburgh Austin Nimmo Smith M.B Edin
WARD—On March 9, at Reading Berks Ernest Ward M D L., M R.C S aged 87

AN EVALUATION OF PUBLIC-HEALTH MEASURES FOR THE CONTROL OF SYPHILIS

AN EPIDEMIOLOGICAL STUDY*

JOSEPH EARLE MOORE
M.D Johns Hopkins

From the Venereal Disease Division of the Medical Clinic, Johns Hopkins University and Hospital, Baltimore

SYPHILIS control, in the modern sense, dates from 1905–10, and the fundamental discoveries of Schaudinn (*Treponema pallidum*), Wassermann, Neisser, and Bruck (a diagnostic test), and Ehrlich ('Salvarsan'). Before 1910, and for lack of these basic scientific discoveries little or nothing could be, or was, done.

In the intervening 40 years, all civilised countries have recognised the danger to public health and welfare imposed by syphilis, and each has engaged in programmes, comprehensive or partial, looking toward its control and, hopefully, to its eventual eradication. Leadership in the development and application of such programmes was taken first in Scandinavia, and more recently, within the last 15 years, in the United States.

Stimulated by recent advances in knowledge, many public health administrators view the future with extreme optimism. They believe that the application of existing knowledge will effect control of this disease and perhaps eventual eradication. It is proposed here to review past experience, with a view to determining whether this optimism is well founded. To this end it is pertinent to examine (1) available data which reflect incidence of syphilis in human populations in the years prior to 1910 before scientific measures of control were applied, (2) the principal factors which determine fluctuations in incidence and its trend during this period, (3) the extent to which these factors are still operative in the modern period since 1910, and (4) the additional effect of measures represented by advances in knowledge in the modern period.

The geographical areas and the time periods for which morbidity and mortality rates from syphilis are available are extremely limited. Moreover, completely accurate information as to morbidity and mortality of the group of venereal diseases is prevented by the social implications of their method of transmission, and, in the case of syphilis at least, by its biological, often nearly symptomless course. Legal requirements as to reporting morbidity and mortality to the health authorities have differed widely in various countries in different parts of the same country, or from time to time within a particular community. Epidemiological data are often confused by consolidation of the entire group of diseases, because of their common mode of transmission, and without regard to separate infectious entities. The trend of "venereal disease" incidence does not necessarily express the trend of incidence of a particular infection, since the rate of one may remain stationary, or even rise, while the rate of another falls—e g, gonorrhœa as compared with syphilis.

The Public health Implications of Early versus Late Syphilis

For practical epidemiological purposes, syphilis is not one but two diseases. One of these, early syphilis (i e, the first 2 to 4 years), represents an acute infection. Infectiousness is concentrated largely within the first year, diminishing rapidly thereafter so that by the end of the fourth year the risk of transmission from one adult to another has almost, if not entirely, disappeared. The other, late syphilis (i e, of more than 4 years' duration), is a public health problem comparable in importance to such non infectious conditions as hypertension and cancer.

It is necessary at the outset to distinguish clearly between the epidemiological terms "incidence" and "prevalence." An attack upon early syphilis should be calculated to break the chain of infectiousness, thereby reducing the *incidence* of fresh infections, and ultimately, within a generation or more, to reduce also the reservoir (i.e, *prevalence*) of late syphilis. In the following discussion, major interest lies in incidence—the rate and extent of dissemination of syphilitic infection.

The public health objective may be clearly stated by changing only three words in the remarks of Frost (1937) on the control of tuberculosis:

> 'It is not necessary that transmission be *immediately* and *completely* prevented [Italics are Frost's] It is necessary only that the rate of transmission be held permanently below the level at which a given number of infection spreading (i e, 'open') cases succeed in establishing an equivalent number (of 'open' cases) to carry on the succession. If in successive periods of time, the number of infectious hosts is continuously reduced, the end result of this diminishing ratio, if continued long enough, must be extermination of the *treponeme of syphilis*.' [Italicised words are the three I have substituted.]

Unavoidably, however, a public health attack is simultaneously directed at late syphilis as well—here without major influence upon incidence (in the epidemiological sense), but instead for the purpose of preventing or treating late complications and thereby minimising invalidism, death, and community cost.

This elementary epidemiological recognition of the division of syphilis into two separate entities has been laggard in application to public-health practice. Where incidence and prevalence data have been collected, it has been customary to record all syphilis as a group, without distinction between its two epidemiological types. In England and Wales, for example, figures as to incidence of early syphilis as such are available only since 1932, in the United States as a whole, only since 1941.

There are exceptions to this epidemiological confusion in various countries and in certain small populations, notably military rather than civilian, though the entanglement is so serious as to give the epidemiologist pause in evaluating long term trends.

EARLY DATA AS TO MORBIDITY AND MORTALITY

In civilian as opposed to military populations, there is therefore singularly little information as to trend of incidence of syphilis until very recent years. It is known (Hirsch 1885, Bloch 1901), without statistical documentation, that the infection spread in major epidemic fashion over Western Europe in the late 15th and early 16th centuries, and thereafter over the entire world, and that from time to time since there have been minor epidemics or major endemics (Scotland mid-17th century, Scandinavia, early 18th century, Serbia, early 19th century).

It is also established, on reliable clinical testimony, though again without statistical proof, that the characteristics of the disease have undergone a profound change in the 450 years of its recognised history. An often rapidly fatal infection has evolved into one of exquisite chronicity. Malignant, destructive lesions of the skin, mucosæ, and bones have been replaced by less obvious but more serious cardiovascular or nervous system involvement, or even by almost complete clinical latency. There is indeed some evidence of a change in clinical character in the United States within the last thirty years. The incidence of early asymptomatic neurosyphilis'

---

* The Malcolm Morris lecture delivered at St Mary's Hospital, London on Sept 21 1950. It is appearing also in the March issue of the *American Journal of Syphilis Gonorrhœa and Venereal Diseases*

(abnormal spinal fluids in persons with primary or secondary syphilis), formerly 25–40%, has fallen to a current 5–15%.

THE TREND OF INFECTION 1865–1910 AS REFLECTED BY MILITARY DATA

If civilian data are lacking, something may be learned of intermediate or long term trends from military population groups. I have elsewhere attempted such a study (Moore 1951a), of which only brief excerpts are possible here.

The importance of syphilis to armies has been apparent since the first 16th century epidemic in the army of Charles V. Most of the major armies and navies of the world have morbidity data dating from the period 1865–80. These are recorded in detail by Haustein (1937) and Hinrichsen (1944, 1945) and for the United States Army by Siler (1943).

One must first inquire as to the extent to which military data may be used as an index of the incidence of syphilis in the civilian population from which military personnel are drawn or with which they are associated. To employ them for this purpose, one should be cognisant of certain facts and assumptions which I have outlined in detail elsewhere (Moore 1951a). The evidence permits, I think, the tentative conclusion that both in peace and war time, *the military incidence of fresh infections* is at least a rough index to prevalence, and perhaps to incidence as well, in the civilian community in which the military command is stationed.

Information is available for nine major armies of Western Europe, and for the United States. In most of Europe, the period chosen was, after the Franco Prussian War of 1870, one of uninterrupted peace. I shall here present detailed incidence curves for only three of the armies studied — Prussian, British, and United States. These are shown in figs 1–3. In all is observed the same downward trend of *incidence of syphilis*.

The percentage change in incidence of syphilis in these several armies during the last half of the 19th and first decade of the 20th centuries is summarised in fig 4. In all the armies studied, except the Austro Hungarian, Russian, and Italian (in which there was an increase), there was a downward trend from the beginning of the period to its end, ranging from 38% in the Prussian to 80% in the British armies.

INFLUENCE OF WAR ON SYPHILIS INCIDENCE IN MILITARY POPULATIONS

Making all allowances for their partial unreliability, the foregoing data suggest strongly that in the period 1865–1910 there was a spontaneous decline in the incidence of fresh infections with syphilis in most of the armies of Western Europe and of the United States, and, by implication, in the civilian populations of the countries. It is important to note that, excepting the United States, Russian, and Italian armies (the latter two engaged in the Russo Turkish War of 1877–78, the Russo Japanese War of 1904–05 and its concomitant and subsequent internal Russian revolution, and the Italian African adventures of 1887–1900) the other major *armies were at peace*.

It is a commonplace, however, that in military populations (and in civilian as well) the incidence of syphilis rises in war time. For two European armies, the belligerent French and the neighbouring neutral Dutch, this is well shown for *World War I by fig 5*, from which is to be noted not only the abrupt rise during hostilities, but also the equally abrupt post war fall to or even slightly below pre war levels.

In fig 6 are shown, for the United States Army (limited to personnel stationed in the *continental United States* and excluding troops on foreign service), three decades of war and post war (Civil War, 1861–71, World War I 1914–22, World War II, 1939–49). Here, too, appear war or immediate post war peaks of incidence on each occasion, *falling within 4 years to or below pre war levels*

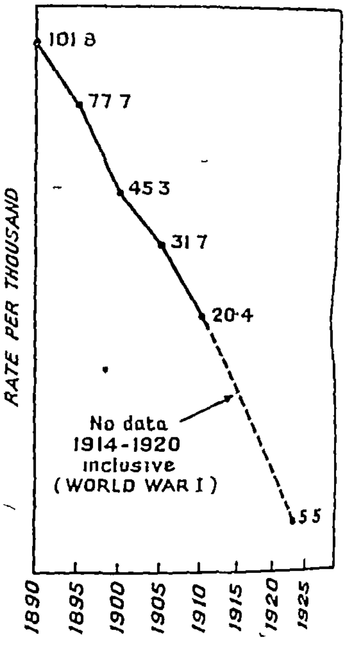

Fig 2—Incidence of syphilis (primary and secondary) in the British army (at home) 1890–1925 (Haustein 1937) Average strength of army about 100,000.

Note that while the starting base line incidence figure varies in different armies (Prussian about 30 per 1000, U S A about 70 per 1000, British about 100 per 1000) as shown in *figs 1, 2, and 3*, the shape of the falling curves of incidence is about the same.

Note also that in the British army (at home), the *rate of fall* was continuous but *apparently not* accelerated in the *modern era* 1910–25.

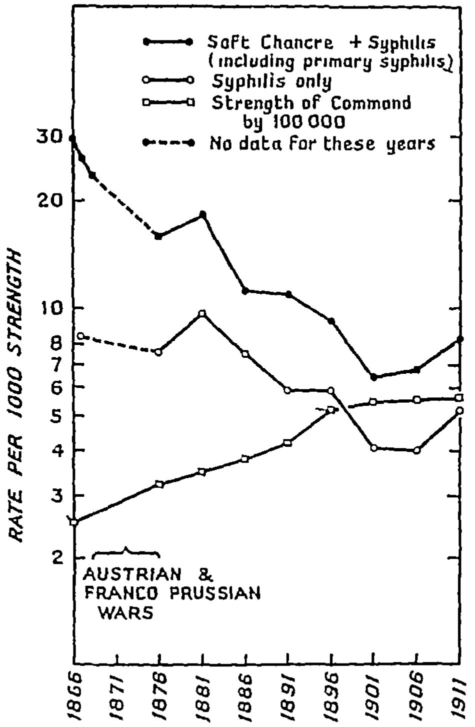

Fig 1—Incidence of syphilis in the Prussian army 1866–1913 (Haustein 1937)

In this and similar curves showing military rates I have shown the average incidence rate by quintades, in order to smooth minor fluctuations. The average is based on the sum of the rate per 1000 strength for each of five successive years, divided of course by 5, *and the years recorded on the base line of each chart represent the mid point of the quintade*.

An important difficulty in acceptance of pre 1910 military rates arises with regard to chancroid. In certain armies (e g, the Prussian, according to Haustein), primary syphilis was at times or even regularly included during the pre laboratory period in question, under the diagnostic heading 'soft chancre with bubo.' Where this is probably true, I have constructed separate curves for syphilis alone and for syphilis plus chancroid, which (except in two armies, Austro Hungarian and Italian) show remarkable parallelism. For armies reporting primary and secondary syphilis as such these data alone have been used

These data offer a strong suggestion that the fall in incidence of syphilis observed in most major European armies and in the United States in the period 1865–1910 depends on the usually observed post-war fall in incidence, a phenomenon not directly related to syphilis control measures This is further suggested by crude United States Army rates from 1820 to 1940, shown in fig 3 Here there is first a fall, probably representing the aftermath of the war of 1812 (if the data could be extrapolated backward), with rises and falls during and after each succeeding war † One suspects that if European data were available from, say, 1750 to the present, an initial period of low incidence might have been replaced by fluctuating peaks of high incidence, dating from the major internal and external disturbances initiated by the French Revolution in 1789 and ending (temporarily) with the Franco Prussian War in 1871

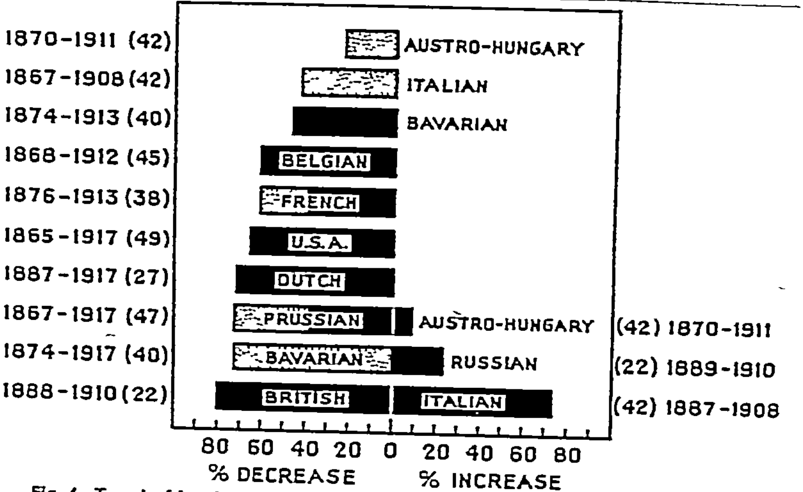

Fig 4—Trend of incidence of syphilis in major armies 1865–1913 (Haustein 1937)

In this chart the solid black blocks represent syphilis only, the stippled blocks syphilis plus chancroid (see text for explanation) For certain armies (Bavarian, Prussian, French, Italian, and Austro Hungarian), both sets of data are shown. In all except the Austro Hungarian and Italian armies, both rates fall in approximate parallel. For the two latter, the chancroid rate fell slightly but that for syphilis increased Perhaps this phenomenon reflects both a higher incidence of chancroid in the Mediterranean basin than elsewhere in Europe (certainly true during World War II), and more early diagnostic confusion between syphilis and chancroid in these two armies than in others

Note that during the period in question 1865–1913, and after the conclusion of the Franco Prussian War in 1871, all the countries here represented were at peace except Russia and Italy, each of which, engaged in war, showed a rise in incidence

FACTORS POSSIBLY INFLUENCING THE PRE 1910 INCIDENCE OF SYPHILIS

In the absence of knowledge of prevention or of successful treatment methods of syphilis, the only pre 1910 method of control of syphilis attempted in most countries—and this half-heartedly and wholly unsuccessfully—was regulation or repression of prostitution ‡ As a method of syphilis control in civilian populations (perhaps of more value in military groups), this single effort was foredoomed to failure, since, at least in the United States, organised prostitution is not now and probably never has been, the largest factor in the transmission of syphilis § The feminine contact, especially in younger age groups, is usually the casual contact, and if prostitute at all, is often clandestine rather than the inmate of a brothel. The explanation of a falling syphilis rate in the last half of the 19th century must therefore be sought elsewhere

Was the Decline a Natural Phenomenon?

In a stimulating paragraph, Dubos (1950) implies an exciting possible parallel between the two major chronic infections, tuberculosis and syphilis

Not so long ago tuberculosis was the Great White Plague, the 'captain of all men of death' for the white race In Boston, New York, Philadelphia and Charleston —in London, Paris and Berlin—all available statistics reveal tuberculosis mortality rates of 500 or higher per 100 000 inhabitants in the year 1850 Some time around 1860 the number of deaths from the disease began to decrease in Europe and North America, and it has continued to decrease ever since except for brief interruptions in the downward trend interruptions associated with two world wars In 1947, tuberculosis mortality

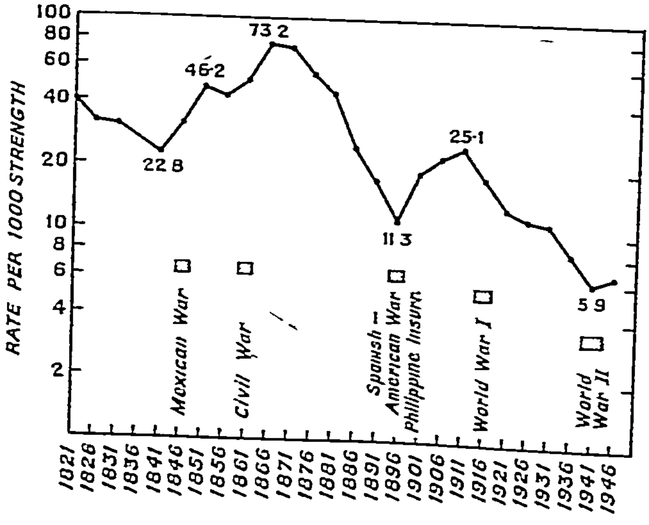

Fig. 3—Incidence of syphilis in U.S. Army at home and abroad 1820–1946 (based on data from Siler 1943)

Note first, in connection with the text argument of spontaneous decline the falling rate 1866–96, analogous to that shown in figs 1 and 2 for the Prussian and British armies During this time period the U S Army had no troops on foreign service

Note next in connection with the text argument on the effect of war on incidence of syphilis the fall in rate 1820–41 (the aftermath of the war of 1812) and the rises and subsequent falls centring around the Mexican War (1845–47), the Civil War (1861–65) the Spanish American Wars, and the Philippine Insurrection (1898–1908) The absence of a rise during World War I is due according to Siler to inadequate reporting from the A.E.F in France

---

† Excepting World War I where the figures are inaccurate because of the failure of reporting from the American Expeditionary Force in France (Siler 1943)

‡ The hospitalised quarantine of patients with early syphilis continued until their open lesions were healed, was practised in only a few countries (notably Norway) and cannot have been a factor in a general European decline

§ This statement may not be true of other countries and other times. Guthe and Hume (see Vonderlehr 1939) lay stress on the importance of prostitution in the spread of syphilis, especially to military groups, and believe it to have been an important factor in civilian infections in France and Russia some decades ago (abnormal spinal fluids in persons with primary or secondary syphilis), formerly 25–40%, has fallen to a current 5–15%

THE TREND OF INFECTION 1865–1910 AS REFLECTED BY MILITARY DATA

If civilian data are lacking, something may be learned of intermediate or long term trends from military population groups I have elsewhere attempted such a study (Moore 1951a), of which only brief excerpts are possible here

Was the Decline a Natural Phenomenon ?

In a stimulating paragraph, Dubos (1950) implies an exciting possible parallel between the two major chronic infections, tuberculosis and syphilis

> Not so long ago, tuberculosis was the Great White Plague, the ‘captain of all men of death’ for the white race In Boston New York, Philadelphia, and Charleston —in London, Paris and Berlin—all available statistics reveal tuberculosis mortality rates of 500 or higher per 100 000 inhabitants in the year 1850 Some time around 1860, the number of deaths from the disease began to decrease in Europe and North America and it has continued to decrease ever since except for brief interruptions in the downward trend, interruptions associated with two world wars In 1947, tuberculosis mortality

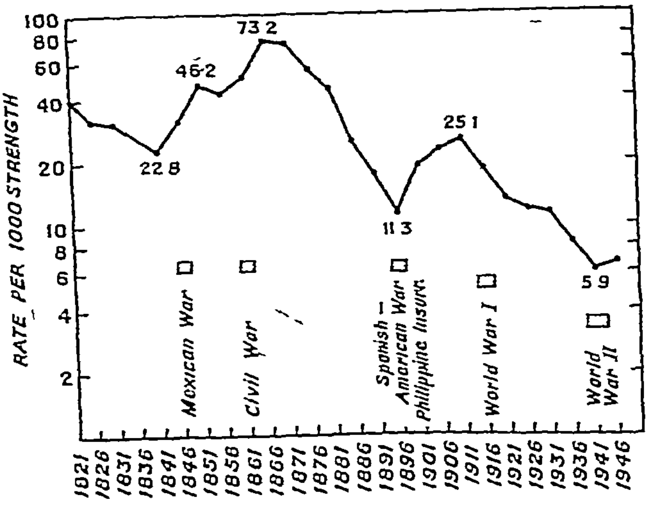

Fig. 3—Incidence of syphilis in U.S Army at home and abroad, 1820–1946 (based on data from Siler 1943)

Note first, in connection with the text argument of spontaneous decline, the falling rate 1866–98 analogous to that shown in figs 1 and 2 for the Prussian and British armies During this time period, the U.S Army had no troops on foreign service

Note next in connection with the text argument on the effect of war on incidence of syphilis, the fall in rate 1820–41 (the aftermath of the war of 1812), and the rises and subsequent falls centring around the Mexican War (1845–47), the Civil War (1861–65) the Spanish American Wars, and the Philippine Insurrection (1898–1908) The absence of a rise during World War I is due, according to Siler to inadequate reporting from the A.E.F in France rates were below 40 per 100,000 population in several countries and were still decreasing Thus, in many places, the toll of deaths due to tuberculosis had decreased more than tenfold in less than a century, a spectacular event that has excited endless discussions among students of public health The decrease began before the discovery of the tubercle bacillus, long before there were available any specific methods of prevention or cure Western civilization is slowly, but perhaps not surely, gaining in its fight over tuberculosis, without being too certain of the circumstances to which it owes its success For equally mysterious reasons scarlet fever is on the wane, fifty years ago a frequent cause of death it is to day a relatively mild disease [As to syphilis] Western civilization took the disease in stride and learned to live with it Indeed, the contagion may have made European culture burn with a brighter light, if it be true, as claimed by certain medical writers, that a correlation exists between syphilis and genius "

---

† Excepting World War I where the figures are inaccurate, because of the failure of reporting from the American Expeditionary Force in France (Siler 1943)

‡ The hospitalised quarantine of patients with early syphilis continued until their open lesions were healed, was practised in only a few countries (notably Norway) and cannot have been a factor in a general European decline

§ This statement may not be true of other countries and other times Guthe and Hume (see Vonderlehr 1939) lay stress on the importance of prostitution in the spread of syphilis especially to military groups, and believe it to have been an important factor in civilian infections in France and Russia some decades ago

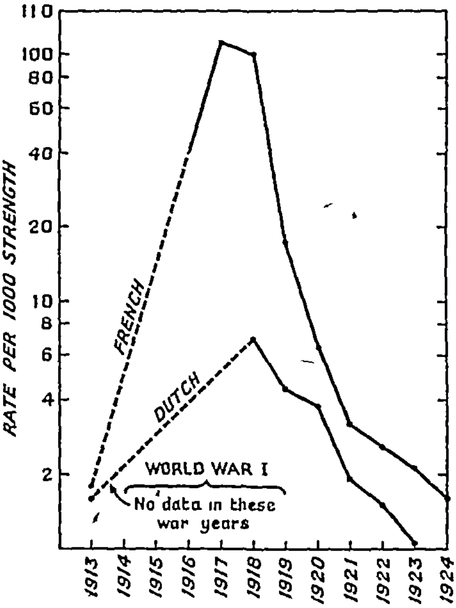

Fig 5—Rise in incidence of early syphilis in a belligerent (French) and neutral (Dutch) European army during World War I (Haustein 1937) Dutch army, all early syphilis, French army, primary' syphilis.

Inherent in this fascinating suggestion is the implication that some degree of change in host parasite relationship has developed in those civilised and syphilised populations which have been subjected to the influence of the infection for 450 years Whether, in turn, this depends on mutations and changes in virulence of the parasite, or on some degree of developing racial immunity in the host, or on both, are speculative questions impossible of proof, and too complicated for discussion here

Was the Decline Related to Improvement in Socio economic Conditions?

Here we begin to be on somewhat firmer ground It has long been known that the morbidity and mortality of syphilis, as of tuberculosis, are related to socio economic conditions—poverty, overcrowding due to poor housing, lack of recreational facilities, and the like One of the first studies is a report from the Registrar General in which (fig 7) mortality from syphilis plus paresis, tabes dorsalis, and aneurysm in persons 20–65 years of age in 1930–32 is related to five broad occupational groups (Registrar General 1938) There is a consistent rise with decreasing socio economic status

Schamberg (1945) has made ingenious use of data provided by Usilton et al (1945) concerning the prevalence of syphilis (positive serological tests) among United States male selectees of World War II aged 18–37, and in relating this to tuberculosis mortality in the United States by broad socio economic groups The data, scale adjusted for better comparability, are shown in fig 8 There is a sharp increase both in morbidity of syphilis and mortality of tuberculosis with lowering socio economic status Among unskilled labourers, the prevalence of syphilis is three times as high, and the mortality of tuberculosis fourteen times as high as among professional workers (i e, physicians, attorneys, teachers, architects, &c)

The relationship of syphilitic infection with socio economic status is clarified further by the data of Kinsey et al (1948) on the sexual behaviour of 5300 white United States males There is reason to believe that the information they provide is applicable, at least in broad general principle, to males in any Western civilisation Exposure to the possibility of syphilitic infection through non marital sexual intercourse varies directly with educational level and occupational class, as may be seen from fig 9 (The data are " double entry," based on both the parental class in which the subject originated and the ultimate class into which he independently migrated The relative frequencies of non marital intercourse shown are for young males, aged 16–20, but the same relative positions of frequency hold good for all ages) Potential risk of infection with syphilis (if each episode of non marital intercourse is accepted as a risk) is about ten times greater in persons whose education is limited to primary or even secondary school than in those of college or university level, and about sixteen times greater among unskilled labourers than among professional men Moreover, as Kinsey points out, males of low educational and economic groups are much more liable to exposure with many, rather than few, partners, and the many partners are more likely to be drawn from female groups, including prostitutes, who themselves receive many, rather than

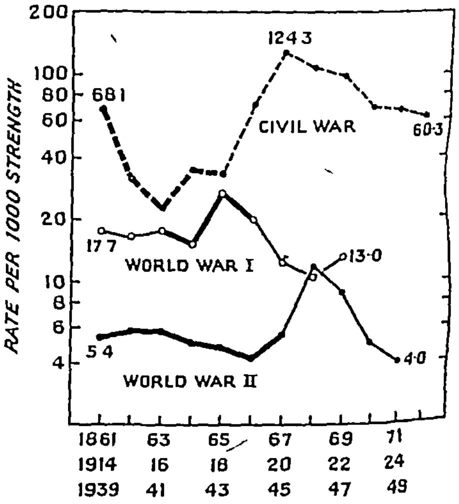

Fig 6—Incidence of early syphilis in the U.S Army at home (troops overseas excluded) during three widely separated decades surrounding three major wars (Surgeon-General, U.S. army) Figures for World War I include cases existing prior to service. Those for World War II exclude such cases.

Note that during the Civil War and World War II, the rise was post war, rather than during mobilisation and/or hostilities, for unexplained reasons, the World War I rise was in an actual combat year Note also, in each case, the fall in rate to or below pre war level within a quintade after the peak

Finally, as pertinent to the effect of modern control measures, note that the starting base line in 1861 was approximately 6 8 per 1000 strength, in 1914, 17 per 1000, and in 1939, 5 4 per 1000 Note further that the rates of decline after World Wars I and II are substantially steeper than after the Civil War, but that the 1946–49 decline is identical in shape to that of 1918–21 suggesting that penicillin has perhaps provided no special advantage

Compare this curve for World War II (limited to the U S Army at home) with that of fig 17 (entire U S Army, including troops overseas) The rise in troops at home was only from 4 2 to 11 5 per 1000 strength for the army as a whole from 5 8 to 54 per 1000 This comparison strengthens the suggestion that the incidence of syphilis in a military command may be related to that in the immediately surrounding civilian population few, males. The infectious risk is thus many times multiplied.

These and other data, directly linking the incidence and prevalence of syphilis to low educational and socio-economic status, suggest the possibility that the decline in syphilis in Western Europe and the United States in the period 1865–1910 was related, in whole or in part, to gradual improvement in both educational and general economic conditions during this period. and that any further decline since 1910 may also, at least in part, be so attributed. To some extent, this is certainly true.

Special Influence of War and Population Instability on the 1865–1910 Decline

It has been many times shown, and I have emphasised the fact here, that the incidence of fresh infections with syphilis always rises in a country engaged in war, and also in neighbouring or even non neighbouring neutral countries. The same phenomenon is observable in periods of serious internal political or economic unrest. The war-time rise is always followed by a post war decline, which, within variable periods, brings incidence to or below pre-war level.

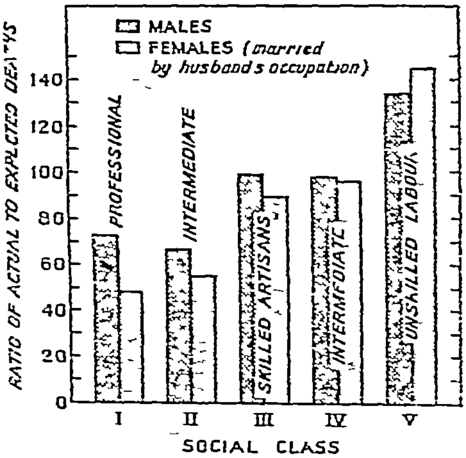

Fig 7—Relation of socio-economic status to the mortality of syphilis in England and Wales 1930–32 (Registrar-General 1938). Ratio of actual to expected deaths (syphilis tabes paresis and aneurysm) by social class ages 20–65.

The factor common to war and internal political or economic unrest is population instability. Large numbers of males in military service, and of males and females in war industry, are dislocated from their homes. Often constantly on the move, they are likewise dislocated from their customary sexual partners marital or non marital. There is reason to believe (Kinsey et al. 1948) that individual sexual behaviour, in terms of frequency of sexual intercourse, varies little whether a given population group is stable or unstable, at home or away from home. For purposes of illustration, one may assume that at home the average young United States male, with an average intercourse frequency of 1.2 per week (Kinsey), has his customary 62 contacts per year with one or a few regular partners. Away from home, and constantly moving from one locale to another, he may still achieve the same number of contacts, but, as he is temporarily divorced from family and friends, the female partners are of necessity many rather than few, casual rather than regular, and themselves more likely to be exposed to contact with many, rather than few, men. The infection risk is thereby enormously multiplied.

With demobilisation of armies, and shift from unstable war time to peace time industry, relative population stability is once more restored, regular sexual contact with a few close associates replaces casual contact with many, risk of infection decreases, and the incidence of syphilis falls.

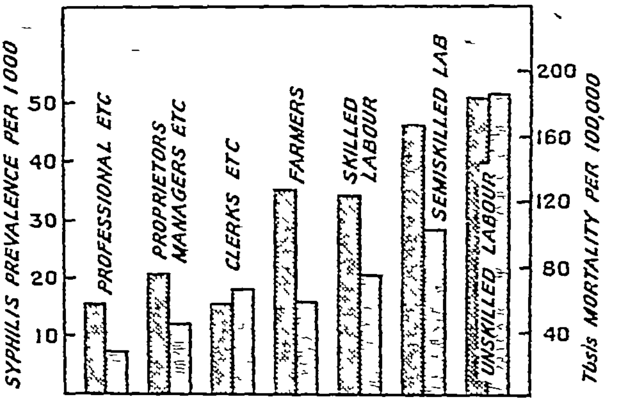

Fig 8—Relation of socio-economic status to the prevalence of syphilis and mortality of tuberculosis (from data gathered by Schamberg 1945)

Indeed, this factor of population stability is almost certainly operative in peace-time as well, and it largely explains the fact that in countries with little internal population shift (e g, Scandinavia, which is also specially distinguished by relatively high educational and socio economic standards), incidence and prevalence of syphilis have always been low as compared with rapidly growing countries (e g., the United States), where migratory labour has been, and still is, an important social phenomenon.

TREND OF INCIDENCE OF SYPHILIS SINCE 1910 IN CIVILIAN AND MILITARY POPULATIONS

With 1910 we enter a period in which civilian, as well as military, data begin to become available, and in which, moreover, scientific methods for the control of syphilis began to be applied with ever increasing vigour. It should therefore be possible to determine whether modern methods of syphilis control are of value, and perhaps even to estimate which of them has had greatest effect.

Trend of Infection in Civilian Scandinavia

In Denmark and Norway, and to a lesser extent in Sweden and Finland, the trend of syphilis morbidity is known, with apparently a high degree of accuracy, since about the mid-19th century (Clarke 1936, Guthe 1945). The data from Copenhagen, shown in fig 10, may be taken as an example. Here are shown the total number of cases of acquired syphilis reported from 1877 to 1944. Having in mind the absence of effective control measures before 1910, and the probable gradual influence of a

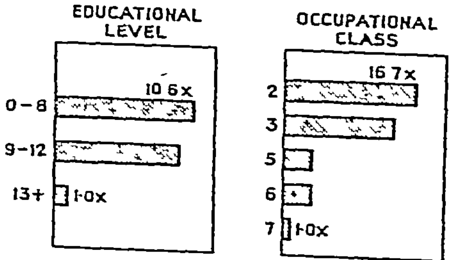

Fig 9—Frequency of extramarital sexual intercourse in males of varying educational level and occupational class (socio-economic status). Reproduced by permission from Kinsey et al. (1948).

Under Educational Level, the figures 0–8 represent persons whose education is limited to primary school level, 9–12 to secondary school, 13— college or university. Occupational Classes represent gradations between unskilled labour (2) and professional groups (7).

Frequencies are relative to the unit 1.0x.

vigorous control campaign beginning in Denmark and Sweden at about that date, one is struck by the relative stability of the Copenhagen curve from 1877 to 1919 (within a fluctuant range of 277–683 per 100,000 population). Beginning in 1919, there was a precipitous decline in incidence in Copenhagen (and also in Sweden, as is shown in fig. 11), from a peak of 527 to an average low level of 30–40 per 100,000 population in 1932–42. With the German occupation of Denmark in World War II, the rate rose abruptly to or above its previously recorded peak, and only began to fall once more in 1947.

Before accepting the premise that the Danish and Swedish declines in incidence were due to their vigorous control programmes, the cautious epidemiologist will note that both in Norway and in England and Wales, each of which countries followed the Danish and Swedish example only to the extent of an educational programme for the laity and provision of free treatment for all who wished to receive it, there was also a fall in incidence after World War I. In Oslo (fig. 12) the decline was from 360 per 100,000 population in 1919 to 30 per 100,000 in 1933 (Clarke 1936). In England and Wales (fig. 13), there was also an apparent downward trend in incidence from 1918 to 1939 (from a peak of 42,805 cases in 1920 to a low of 11,319 cases in 1940), though the fall was neither so abrupt nor so complete as in Scandinavia. In Britain, too, there was a sharp rise, especially in fresh infections, coincident with the outbreak of World War II.

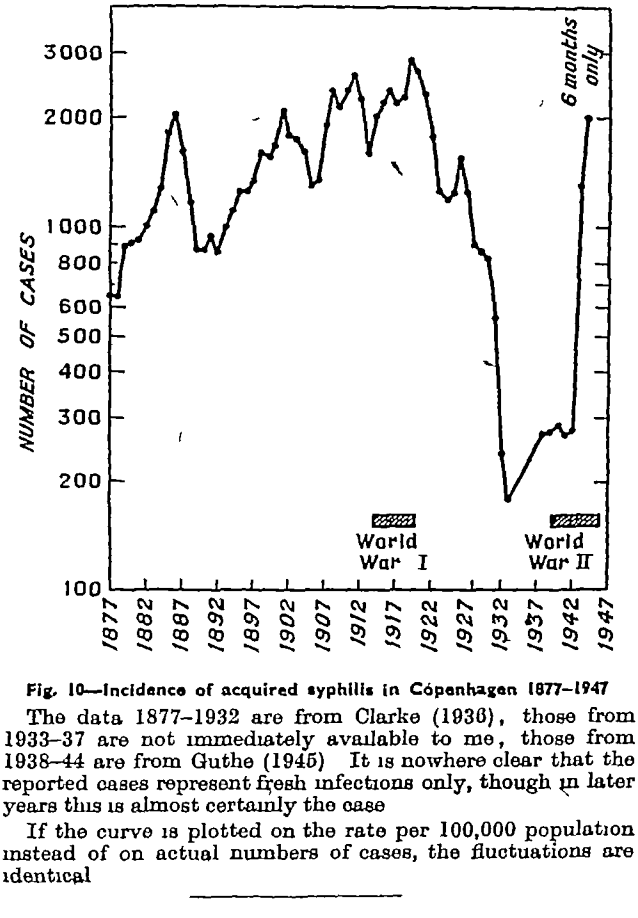

Fig. 10—Incidence of acquired syphilis in Copenhagen 1877–1947

The data 1877–1932 are from Clarke (1936), those from 1933–37 are not immediately available to me, those from 1938–44 are from Guthe (1945). It is nowhere clear that the reported cases represent fresh infections only, though in later years this is almost certainly the case.

If the curve is plotted on the rate per 100,000 population instead of on actual numbers of cases, the fluctuations are identical.

Parenthetically, there was a simultaneous and nearly parallel fall in the incidence of congenital syphilis in Copenhagen (fig. 14), where the control programme was vigorous, and in England and Wales (fig. 15), where it was not.

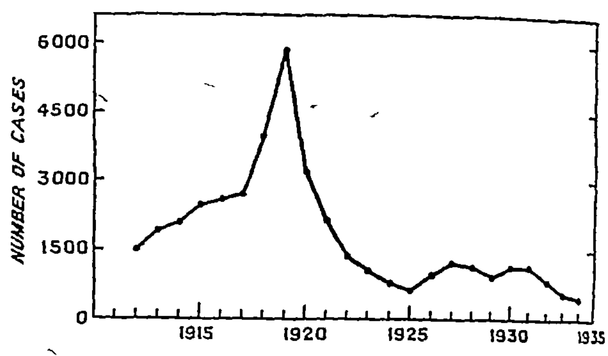

Fig. 11—Incidence of syphilis in Sweden 1912–35 (Clarke 1936)

The control programme here was as vigorous as in Denmark. Note that the rise during World War I was proportionately much greater than in Copenhagen, but the post-war fall was equally swift.

A similar but less well documented decline in incidence of fresh infections with syphilis also occurred in other countries of Western Europe in the period 1919–40. This was perhaps due in part to sociological changes affecting sex habits following World War I, in part to acceleration by control programmes.

Nevertheless, and disregarding the evidence from other countries, the remarkable decline in Denmark and Sweden, observed to a greater extent than elsewhere in the civilised world, was naturally attributed to the detailed plan of venereal disease control in these countries, which has been so well described by Clarke (1936) and many others. The Scandinavian plans have served as the basis for similar and even more extended programmes in other nations, notably the United States.

THE UNITED STATES SYPHILIS CONTROL PROGRAMME, WITH PARTICULAR REFERENCE TO THE DECLINE SINCE WORLD WAR II

Although the Armed Services of the United States possessed vigorous control programmes in both world wars, and to a considerably less extent in the interval between them, a nation-wide effort at control was inaugurated only in 1936 by Thomas Parran, then surgeon general, United States Public Health Service (Parran 1936, 1937). His efforts led to the passage by the Congress of the National Venereal Disease Control Act in 1938, to the continuing appropriation of Federal funds for this purpose, and to the stimulation of similar appropriations by State and local communities. For the first year of operation, the Federal appropriation was $3 million, gradually increased to or above its current annual level of about $16 million. It is estimated that the total United States expenditure (Federal, State, and local) over the past 13 years for civilian venereal disease

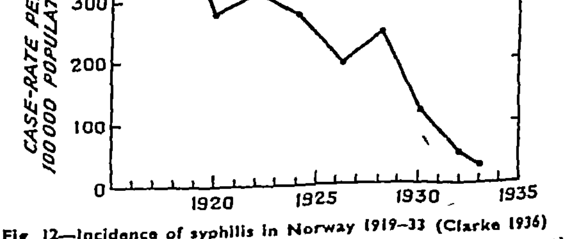

Fig. 12—Incidence of syphilis in Norway 1919–33 (Clarke 1936)

In Norway, as in England and Wales (see fig. 13), the control programme was much less vigorous than in Denmark and Sweden, but in these two countries, the incidence of syphilis also declined. In Norway the rate of fall was not so abrupt as elsewhere in Scandinavia but the end low point in 1933 was about the same.

control is in excess of $350 million, when the Armed Services are included, the figure probably exceeds $450 million.

The United States venereal disease control programme is primarily directed against syphilis, hopefully but less enthusiastically against gonorrhœa and chancroid, and hardly at all against the lesser venereal infections. Implemented in the United States by the establishment of special venereal disease control divisions in Federal, State, and local health departments and in the Armed Services, it is based on six major avenues of attack. Pursued with varying intensity, these are:

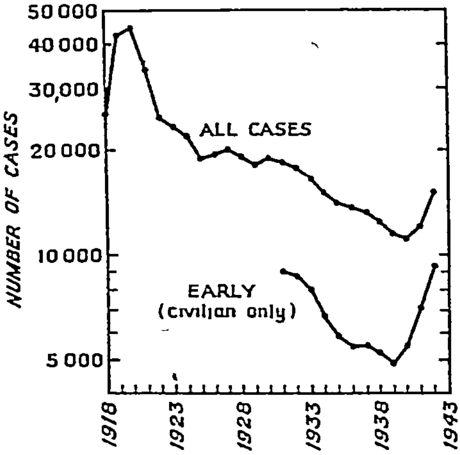

Fig. 13—Incidence of syphilis in England and Wales 1918–42 (Ministry of Health). Cases of syphilis dealt with for the first time at treatment centres.

In the absence of a system of notification, these data are not comparable with Scandinavian figures. Treatment centre statistics vary with economic conditions and are only a rough index to community status.

Note that until 1931, the curve is based on all syphilis, early and late, and is therefore inaccurate both as to incidence and prevalence, especially since there was no organised programme of case finding. Nevertheless it may be guessed that there was a decline in incidence, which, though starting from a far higher base-line in 1918 than that in Scandinavia, was perhaps roughly parallel with the Norwegian decline.

---

1 Methods planned to reduce the number of potentially infectious contacts by modification of human behaviour—i.e., an attack on the "vector" of venereal disease, sexual promiscuity:

- A. Religious appeals.
- B Education of the population both as to sex and venereal disease (of young people in schools, of the public at large, of military personnel, and by various techniques including posters, pamphlets, lectures, press, radio, and motion pictures).
- C Improved housing (relief of overcrowding).
- D The provision of improved recreational facilities for youth.
- E Law enforcement in repression of organised and clandestine prostitution and of facilitators thereof.
- F Efforts at the rehabilitation of promiscuous girls (similar efforts in males are conspicuous by their absence).
- G Punishment for the acquisition of venereal disease (especially in the Armed Forces).

2 Methods planned to reduce the probability of infection if exposure occurs:

- A. Mechanical, chemical, and chemotherapeutic prophylaxis.

3 Methods planned to improve the diagnosis and treatment of infected persons.

- A. Improved undergraduate and postgraduate medical education.
- B Improved methods of laboratory diagnosis.
- C Improved methods of the use of chemotherapeutic agents and the introduction of new ones.

4 Methods planned to promote diagnosis and treatment:

- A. Increase in the number of serodiagnostic laboratories and their ready availability to physicians without cost to the patient.
- B Increase in the number, and improvement in the calibre, of treatment centres, and their ready accessibility without, or at minimum, cost to the patient.

5 Methods to increase the number of infected persons brought under treatment and to hold them there until completion (case finding and case holding):

- A. Mass blood-testing.
- B The epidemiological approach to the discovery of new cases by examination of familial and sexual contacts of infected persons.
- C Intensive efforts at case holding, to ensure that the maximum number of patients are treated "past the point of infectiousness" or "adequately for cure."

THE RESULTS OF SYPHILIS CONTROL IN THE UNITED STATES

Incidence of Early Syphilis

Only since 1941 are there data from the entire United States concerning the number of cases of early syphilis in the civilian population reported to the United States Public Health Service through State and territorial health departments In earlier years, and then only incompletely after 1919, syphilis was reported without a breakdown between fresh infections and late syphilis. The picture 1941–49 is presented in fig 16, in which are shown the rates per 1000 population. Three curves are presented (*a*) for "open lesion" (i.e., primary and secondary) early syphilis, (*b*) for early latent syphilis, and (*c*) a summation of these two (By administrative

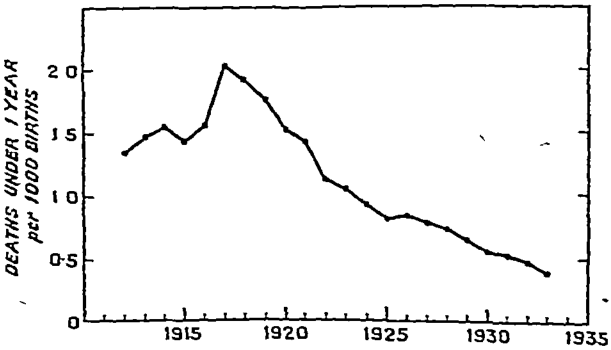

Fig. 15—Mortality-rate of congenital syphilis in England and Wales 1912–33 (Clarke 1936)

Note that the scale here (per 1000 live births) is not comparable to the Danish scale of fig 14 (per 100 000 population) but the same downward trend is apparent, in spite of less vigorous control measures decision, the term "early latent" syphilis is applied to those patients who give a reasonably clear cut history of infection within 4 years, or, as is usually the case, with history lacking, to persons under the age of 25 who are found to be seropositive)

In the 9 year period covered by fig 16, there were reported 730,700 cases of primary and secondary syphilis, and 1,020,000 cases of early latent syphilis—an annual average respectively of 81,200 and 113,300

A point of epidemiological importance to be deduced from the data of fig 16 is that more than one half (actually about 60%) of persons infected with early syphilis do not come under medical care at the time of recognisable infectious lesions, and this in spite of intensive efforts at case finding The reasons for this have been shown (Spoto and Iskrant 1949) to depend in part (at least 35%) on the relatively silent, trivial, and insignificant lesions of early syphilis, which are unrecognised or misinterpreted by the patient or his physician, and in larger part to the patient's ignorance or fear

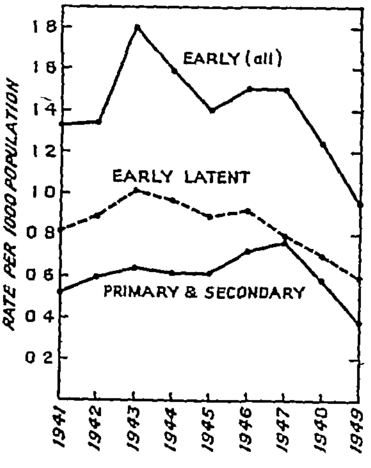

Fig 16—Incidence of early syphilis in U.S civilians 1941–49

Data as to incidence of early syphilis are not available in the United States before 1941 For a discussion of these curves, see text

The demonstrable fact that in the United States, and presumably in other countries as well, more than half of recently infected persons do not reach medical attention during the period of their maximum infectiousness for others is a serious, though not necessarily an insuperable, obstacle to the complete control of the disease Steps to be taken to remedy the situation lie clearly, as will be shown, in increased emphasis on case finding and on lay and medical education

Fig 16 shows also that there was a rise in the incidence of primary and secondary syphilis from 1941 to 1947, especially notable in the two immediate post war years, followed by a decline beginning in late 1947 which has been continuous since From the peak 1947 level, discovery rates have fallen by 34%, from the 1941 base line (if it is a base line) by 16% The decline continued through the first half of 1950 (detailed figures not yet available)

In Fig 17 are shown comparable curves for all early syphilis in the civilian United States population, and for all reported syphilis (mostly early syphilis, since pre existing infection in men inducted into military service is excluded) in the United States Army at home and overseas for the years 1941–49 The scale differs, since the Army rate, among young males, is from five to fifteen times the rate among civilians of both sexes and all ages The sharp post war rise from 1944 to 1947 is much more obvious in the military group, largely because of the inclusion of cases in troops on foreign service, as is the abruptness of the decline since 1947

The fall in incidence rate of early syphilis has attracted much attention within the past 18 months, first as to whether it is a genuine phenomenon, and if so, as to its cause Of these points, more later

THE DISCOVERY OF LATE SYPHILIS

A by product of attempted control of the incidence of early syphilis is the discovery of the prevalence of late syphilis, and the probable effect of this on mortality The rapid increase in the discovery rate of syphilis as a whole (not early syphilis) after 1936, which marked the inception of the control campaign in the United States (and the passage—in Connecticut—of the first of the premarital blood testing laws, which, with similar prenatal laws, now apply in 39 of the 48 States) is shown in fig 18 This rise is a direct reflection of mass blood testing The number of persons newly discovered probably to have syphilis by this procedure can be estimated only, but in the last 12 years must exceed 2 million That most of these had late, rather than early, infections is relatively unimportant, since the application of treatment to these long established cases has almost certainly been a major factor in the reduction, presently to be discussed, in infant and adult mortality rates and in admissions to mental hospitals That the previously undiscovered reservoir of late syphilis in the United States is probably diminishing is further suggested by the curves of fig 19, from 1941 to mid 1949 The discovery rate of late syphilis reached its peak in 1943 (blood testing of all selective service registrants), then fell abruptly, and has levelled off since mid-1947

MORTALITY FROM SYPHILIS

The most careful study of mortality of recent record is that of Kahn and Iskrant (1948) These authors present trends in the United States, beginning with 1933, the first year in which the whole country was included in the vital statistics registration area. The curves are based upon tabulation of death certificates by the National Office of Vital Statistics As deaths due to

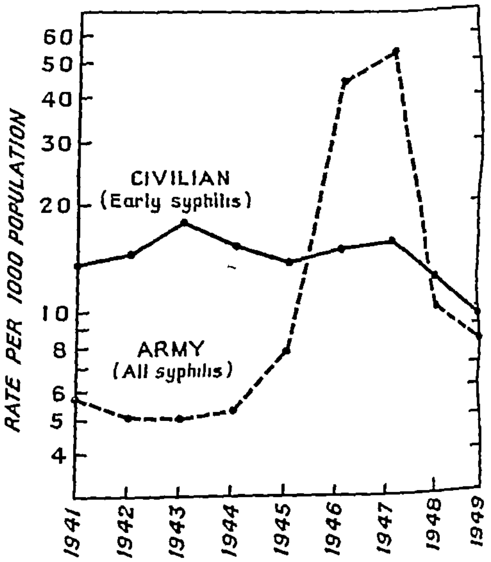

Fig 17—Military versus civilian incidence of early syphilis in the United States 1941–49 (Surgeon-General, U.S Army, U.S. Public Health Service)

The U S army rate includes all syphilis, latent and late as well as early, but since inductees (cases existing prior to service) are excluded, 90+% of all cases represent fresh infections

That the military rate is about 10 times the civilian rate is based on the selected population of the former (all young males) as contrasted with the inclusion of both sexes and all ages in the latter

Much of the sharp post-war military increase is accounted for by the fact that overseas troops, as well as those at home, are included Compare this curve with that of fig 6, which includes only the U S Army in the continental United States

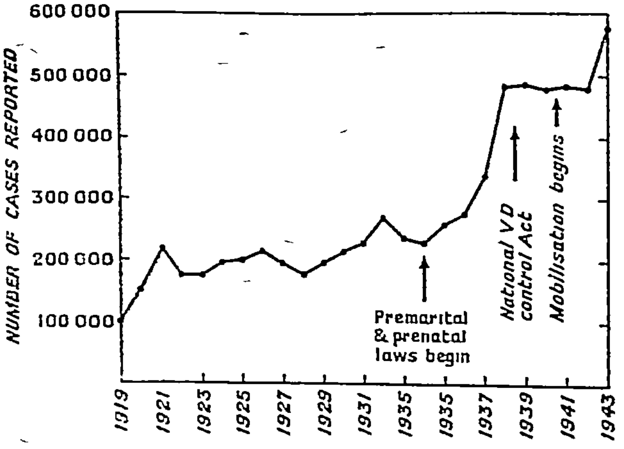

Fig 18—Effect of mass blood testing on the discovery rate of syphilis All cases reported to U.S. Public Health Service (excluding military cases 1941–43)

Mass blood testing was stimulated, in medical agencies and in industry, as early as 1934, but it began in earnest with the rapid passage of compulsory premarital and prenatal blood testing laws in 1936, and with the routine use of blood tests by selective service in 1941

syphilis, the authors include all those in which this disease was recorded by name as the primary cause, plus all those due to paresis, tabes dorsalis, and aneurysm (this latter only since 1939) The death rate so computed is minimal, since it omits all deaths from cardiovascular or neurosyphilis other than the three particularly named or from syphilis of other organs unless syphilis was specifically recorded (e g, hepatitis) It must be emphasised that these recent death rates are in part a reflection of the incidence of syphilis some two decades earlier and in part a reflection of the effectiveness of modern treatment in preventing death from syphilis

Kahn and Iskrant recognise the inadequacy, deliberate or unconscious, of reporting syphilis as a cause of death, but say

> It seems probable that during this 13 year period, physicians have become more able and more willing to report syphilis as a cause of death, rather than less able and less willing to do so Thus, the downward trend in syphilis rates during the last 9 years is considered to be indicative of real decreases rather than of poorer reporting'

These data have been now brought through 1948 (United States Public Health Service 1950) with total mortality for 1949 estimated, and are graphically shown in fig 20 Separate curves are shown for total mortality from syphilis and for paresis, tabes dorsalis, and aneurysm Each curve, in order to show comparative trends, starts at its approximate peak as of 1933 (except for aneurysm, which was first recorded as a separate cause of death in 1939), percentage figures per 100,000 adjusted on the ordinate The mortality from syphilis as a whole began a definite fall in 1938, the year of passage of the National Venereal Disease Control Act Kahn and Iskrant believe that the downward trend in over all mortality is "highly reliable, since known factors (ageing of the population and redefinition of aneurysm) and probable improved reporting by physicians have all exerted an upward force on the rate during this period"

By an ingenious computation, Kahn and Iskrant estimate further that in 1933 the white population of the United States lost 290,000 years of life from the mortality due to syphilis, whereas by 1944 (allowing for the differences in life tables), this had been reduced to 201,000—a saving of 89,000 life years!

The over all mortality curve from syphilis in adults is further compared in fig 21 with those for infant mortality from syphilis per 1000 live births, and for admission rates to mental hospitals due to syphilis per 100,000 population The trend in all is downwards, that for infant mortality the most precipitous

Although the death-rate from syphilis is apparently decreasing in the United States, it is emphasised (United States Public Health Service 1947) that in 1944 (at a level of 11 3 per 100,000 population) there were still more recorded deaths from this cause than from all the following diseases combined poliomyelitis, rheumatic fever (probably excluding rheumatic heart disease, though not so specified) malaria, diphtheria, acute bacterial meningitis, typhoid and paratyphoid fevers, pertussis, scarlet fever, puerperal septicæmia, and dysentery (whether including the group of infant diarrhœa not specified) Moreover, Aufranc (1951) points out, that in spite of these declines, there were still, in 1949, among the American people, 14,000 infantile infections, and 6000 psychiatric hospital admissions due to syphilis

EVALUATION OF COMPONENT PARTS OF A SYPHILIS CONTROL PROGRAMME

The Venereal Disease Division of the United States Public Health Service has prepared or stimulated many studies of the efficacy and relative cost of particular control measures Holding other factors so far as possible equal, a public health experiment can be varied so as to permit at least a short term "spot" estimate of its usefulness I have elsewhere (Moore 1951b) considered the available evidence in some detail, and will repeat only brief conclusions here.

Most of *the methods planned to reduce potentially infectious contacts* (*group I above*) represent community, rather than primarily medical or public health, effort Some of these (religious appeals, elevation of general educational, socio economic, and recreational standards) are long-term rather than short-term and are largely intangible of measurement Specific education of the public as to syphilis is difficult of evaluation but demonstrably effective and essential, even though expensive Repression of prostitution is of some, but not decisive, value, especially for civilian populations. Punishment is useless and actually harmful

Methods to reduce probability of infection if exposure occurs—i e, prophylaxis—require a brief word Chemical prophylaxis, as used in military practice for 40 years,

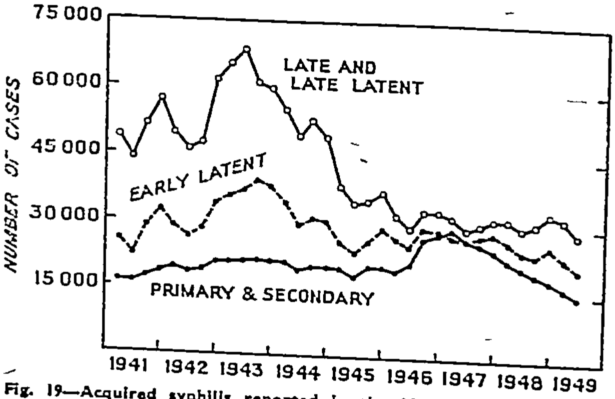

Fig. 19—Acquired syphilis reported in the United States 1941–49 Known military cases excluded.

Note the peaks of late, late latent and early latent syphilis in 1943 These are for the most part cases discovered by mass blood testing The fall in late syphilis since 1943 suggests that the reservoir of previously undiscovered cases may be diminishing

It is difficult to explain why the curve for early latent syphilis has not paralleled the downward trend of manifest early syphilis since early 1947

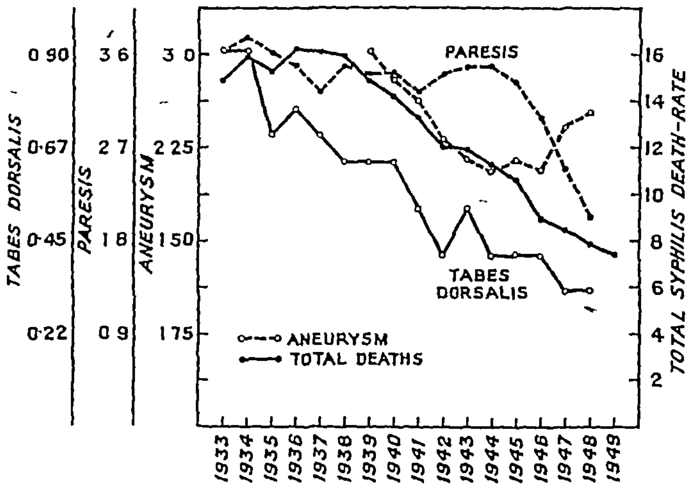

Fig 20—Reported mortality from acquired syphilis in the United States 1933–49 (curves adapted from U S Public Health Service 1947, 1950) Each curve is per 100,000 population, the ordinate percentages adjusted so that all curves start at about the same point.

See text for description There are curious discrepancies between the curves for, for example, tabes dorsalis, paresis, and aneurysm The fall in tabes deaths began in 1934, that in paresis not until a decade later Both of these have been continuous, while the curve for aneurysm, after an initial fall, seems to be rising again

---

is not applicable in civilian life, and is in any case nearly worthless and should be abandoned Mechanical condom prophylaxis is certainly of value, but its effect cannot be measured Penicillin prophylaxis by the oral route is effective against gonorrhœa, but not yet shown to be applicable to syphilis In civilian as opposed to military populations, any form of prophylaxis is a weak reed to lean upon

Methods to improve diagnosis and treatment of infected persons are of major importance In the United States, medical education as to syphilis, both undergraduate and postgraduate, has greatly improved in the last two decades New and improved methods of serodiagnosis have been introduced—e g, cardiolipin antigen, the discovery of treponemal immobilising antibody Performance of serological tests has been immeasurably bettered by national and local serological surveys New chemotherapeutic methods—at first, improved schemes of use of arsenic and bismuth, and since 1943, the introduction of antibiotics (especially penicillin, but also including 'Aureomycin,' chloramphenicol, and 'Terramycin')—have completely revolutionised the treatment of syphilis

PENICILLIN IN SYPHILIS CONTROL

A special word as to *penicillin* is necessary This drug proved to be effective in syphilis in 1943, had been adopted by the United States Armed Services by late 1944, and was in sufficient supply to become a factor in civilian life by 1946 It has provided a rapid, safe, and inexpensive method of treatment, so much more efficient in mass practice than arsenic and bismuth that these latter drugs have been practically abandoned in the United States It is now established that in primary and secondary syphilis, considered together, the "cure" rate is 80–85% at the end of 3 years, provided the drug is administered in such a manner as to produce a continuous detectable blood level for about 10 days The scheme of treatment does not seem greatly to matter if this requirement is fulfilled Since treatment is quick, safe, non toxic, almost completely painless and inexpensive and causes little loss of time all patients complete treatment For the individual patient the chance of cure is somewhat less, and the risk of infectious relapse and/or reinfection somewhat greater, than if he receives 6 months continuous metal chemotherapy, including 40 injections of arsenoxide and 20 of bismuth For the mass of patients, however, the over all chance of cure is greater, since in pre penicillin United States civilian practice few patients had the optimum amount of metal chemotherapy

In respect of penicillin treatment of early syphilis, however, there is an important unsolved public health problem of infectiousness The cumulative incidence of infectious relapse and/or reinfection (which cannot be clearly differentiated) is at least 10% with any satisfactory system of penicillin treatment so far devised This compares with an incidence of 1 75% (Sternberg and Leifer 1947) in a large series of patients treated semi intensively with 26 weeks' 'Mapharsen' bismuth in the United States Army The issue is raised as to whether the total man days of potential infectiousness due to relapse and/or reinfection after penicillin treatment may not actually be greater than after metal chemotherapy (assuming, of course, which is not the case, that all patients actually completed the desired amount of the latter) If it were not for the troublesome 10% incidence of relapse and/or reinfection, one might expect the general use of penicillin to be reflected in a break in the chain of infection, and a lowering of incidence rate Indeed, this explanation of the recent fall in incidence has been advanced in the United States It has been seriously said, verbally if not in print, that penicillin is the final answer, to be shortly effective in eradicating syphilis altogether or relegating it to the minor status of typhoid fever As yet, however, the epidemiologist is unprepared to accept this glowing optimism He must examine the rest of the evidence

In the United States, *methods to increase the availability of diagnostic and treatment facilities* have been outstandingly successful, and it is for this phase of the programme that most of the syphilis control dollar has been spent It is now possible for an infected person anywhere in the United States to receive comparatively

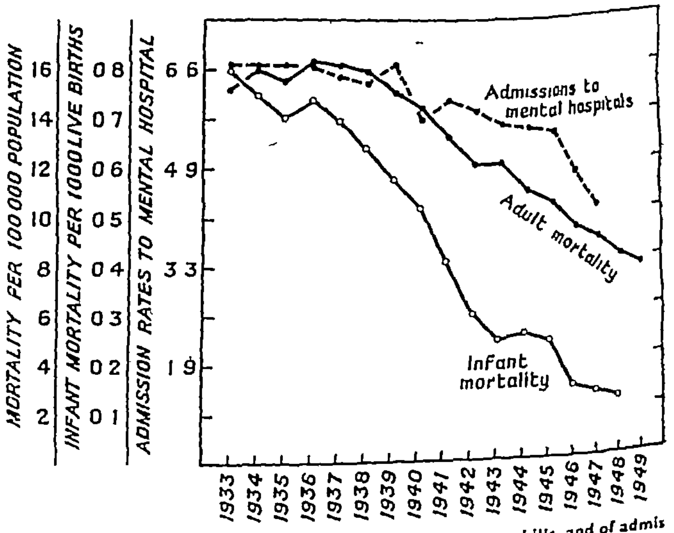

Fig 21—Comparison of adult and infant mortality from syphilis and of admissions to mental hospitals for syphilitic psychosis, in the United States 1933–49 (adapted from U S Public Health Service 1947, 1950)

These curves are adjusted in scale to an identical 100% starting point The declines may be interpreted as a by product of the syphilis control programme, and as the result of discovery of late syphilis rather than early syphilis, with prevention of complications and death by treatment

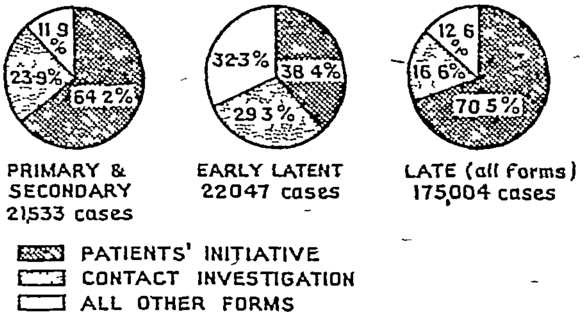

Fig 22—Value of contact investigation in the discovery of syphilis, especially early syphilis in the United States. Showing how previously untreated patients reached medical care (July, 1946 to December 1947) Based on data from 16 States Chicago, St. Louis and New York City

expert diagnostic and therapeutic service at no cost

Methods to increase the number of infected persons brought under treatment (*case finding*) are of great interest and importance to American observers *Mass blood testing*, by custom, regulation, or law, is a development of the last 15 years, and is almost peculiar to the United States It may be estimated that some 50 million Americans have been routinely tested, in medical practice, in industry, in the Armed Services, and in premarital or prenatal tests

An important objection to mass blood testing lies in its non specificity Technical and biological false-positive reactions are frequent, and in certain United States population groups probably represent nearly half of the positive tests discovered. Moreover, the yield of early infectious syphilis is low, and for the purpose of interrupting the chain of infectiousness the method is inefficiently expensive These objections are more than counterbalanced, however, by the discovery of at least a large part of the huge reservoir of late syphilis, by the resultant fall in mortality, and by the educational value of the method

The most significant United States contribution to syphilis control lies in the widespread application of the *epidemiological approach to case finding* To enlightened syphilologists, responsibility for the patient with syphilis has never ended with the patient himself Always it has included the urgent questions "From whom did you contract syphilis?", "To whom may you have given it?" The first demonstration of its value on a nation wide scale, however, proceeds from United States experience of the past 15 years The voluminous literature on the point is well summarised by two brief articles

The first of these, without authorship, emanates from the Venereal Disease Division (United States Public Health Service 1948) An analysis is made of the reasons which brought more than 200,000 previously untreated patients to clinics in widely scattered and wholly representative areas of the United States covering 16 States plus the large cities of Chicago, St Louis, and New York, for the period July, 1946, to December, 1947 The data are graphically presented in fig 22 Of 21,533 cases of primary and secondary (i e, open lesion) syphilis, 64% reported on their own initiative, 24% were individually sought for and found as the sexual contacts of other infected persons, and 12% came for other reasons (usually routine serological discovery) Only 38% of 22,000 patients with early latent (i e, potentially infectious) syphilis came to medical care on their own initiative, 29% because of contact investigation, and 32% for other reasons Of 175,000 cases with late syphilis, 16 6% were brought to care by contact investigation These are imposing numbers

Bauer (1949) adds statistical confirmation of a different sort For each voluntary admission of a patient with early infectious syphilis in 15 areas of the United States, investigators obtained identifiable data as to an average of 2 52 persons exposed but not yet examined, discovered on examination 0 75 persons infected with syphilis, and found 0 19 persons with actual "open lesion" infectious syphilis These are cases which otherwise would fail to come under medical care at all, or at least not until the lapse of years

Each such person with early syphilis discovered and brought under treatment constitutes a fresh break in the chain of infection, which should lead, if continued long enough, to the gradual control of syphilis

DECLINE IN MORBIDITY AND MORTALITY

Is there Evidence of a Decline since 1910?

On the basis of accurate civilian data, the question as to fall in incidence cannot yet be satisfactorily answered except in Scandinavia, and partially in Britain Military information may be added, however In the United States Army, the pre war base line in 1861 was about 68 per 1000 strength, in 1914, 17 per 1000, and in 1941, about 5 per 1000 (see fig 6) Combining this and other military data with Scandinavian and British civilian experience, one may tentatively conclude that the incidence of syphilis in Western Europe and the United States has fallen significantly below its pre 1910 level; and is probably still declining Moreover, although exact figures are lacking to document the statement, it is highly probable that the rate of decline has been greater since 1918 than previously

Mortality in adults has certainly declined in the past 15 years, and in some countries infant mortality appears to be approaching the vanishing point

That the accelerated decline in morbidity did not begin for about 8–10 years after the great discoveries of 1905–10 is accounted for by the inevitable lag in their world-wide application, and by the rise in incidence attributable to World War I It was interrupted temporarily by a similar rise during and after World War II, but has now been resumed.

A fall in mortality did not become apparent, at least in the United States, for nearly a generation after the introduction of metal chemotherapy This delay is certainly due to continuing deaths in the period 1910–38 of patients wholly untreated, or given mercury only, or inadequate arsenic

It is permissible, I believe, to attribute declining morbidity (since 1918) and mortality (since 1938) to the application of modern control methods, especially effective treatment, to millions of persons Nevertheless, a cautionary word should be added that most of these declines occurred during the era of metal chemotherapy (prior to 1946), and there is as yet no convincing evidence to indicate that the rate of decline has been further accelerated in the few years since the introduction of penicillin

Has the Decline been More Abrupt in Countries with Elaborate Control Programmes?

Here there is less firm ground Some of the evidence given above suggests that a fall in incidence occurred, to some degree or perhaps even to the same degree, in countries which, for many of the years since 1910, did little or nothing except to use modern drugs in infected applicants (e g, Norway, Britain) as in countries with more elaborate programmes (e g, Denmark, Sweden, the United States) Available information is too scanty and too short-term to provide an answer

Has the Decline been Sufficient to Promise Eventual Complete Control?

Here the answer, up to the outbreak of World War II, is certainly "No," since that war resulted (as have

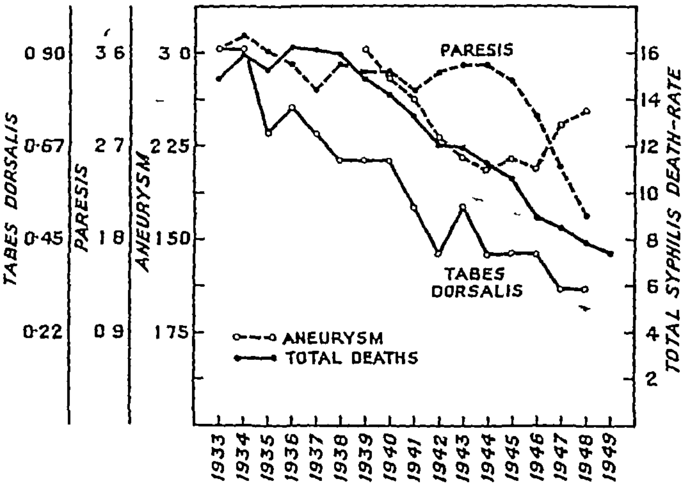

Fig 20—Reported mortality from acquired syphilis in the United States 1933–49 (curves adapted from U.S Public Health Service 1947, 1950) Each curve is per 100,000 population the ordinate percentages adjusted so that all curves start at about the same point.

Methods to improve diagnosis and treatment of infected persons are of major importance In the United States, medical education as to syphilis, both undergraduate and postgraduate, has greatly improved in the last two decades New and improved methods of serodiagnosis have been introduced—e g, cardiolipin antigen, the discovery of treponemal immobilising antibody Performance of serological tests has been immeasurably bettered by national and local serological surveys New chemotherapeutic methods—at first, improved schemes of use of arsenic and bismuth, and since 1943, the introduction of antibiotics (especially penicillin, but also including 'Aureomycin,' chloramphenicol, and 'Terramycin')—have completely revolutionised the treatment of syphilis

PENICILLIN IN SYPHILIS CONTROL

A special word as to *penicillin* is necessary This drug proved to be effective in syphilis in 1943, had been adopted by the United States Armed Services by late 1944, and was in sufficient supply to become a factor in civilian life by 1946 It has provided a rapid, safe, and inexpensive method of treatment, so much more efficient in mass practice than arsenic and bismuth that these latter drugs have been practically abandoned in the United States It is now established that in primary and secondary syphilis, considered together, the " cure " rate is 80–85% at the end of 3 years, provided the drug is administered in such a manner as to produce a continuous detectable blood level for about 10 days The scheme of treatment does not seem greatly to matter if this requirement is fulfilled Since treatment is quick, safe, non toxic, almost completely painless and inexpensive and causes little loss of time all patients complete treatment For the individual patient the chance of cure is somewhat less, and the risk of infectious relapse and/or reinfection somewhat greater, than if he receives 6 months continuous metal chemotherapy, including 40 injections of arsenoxide and 20 of bismuth For the mass of patients, however, the over all chance of cure is greater, since in pre penicillin United States civilian practice few patients had the optimum amount of metal chemotherapy

In respect of penicillin treatment of early syphilis, however, there is an important unsolved public health problem of infectiousness The cumulative incidence of infectious relapse and/or reinfection (which cannot be clearly differentiated) is at least 10% with any satisfactory system of penicillin treatment so far devised This compares with an incidence of 1 75% (Sternberg and Leifer 1947) in a large series of patients treated semi-intensively with 26 weeks' 'Mapharsen' bismuth in the United States Army The issue is raised as to whether the total man days of potential infectiousness due to relapse and/or reinfection after penicillin treatment may not actually be greater than after metal chemotherapy (assuming, of course, which is not the case, that all patients actually completed the desired amount of the latter) If it were not for the troublesome 10% incidence of relapse and/or reinfection, one might expect the general use of penicillin to be reflected in a break in the chain of infection, and a lowering of incidence rate Indeed, this explanation of the recent fall in incidence has been advanced in the United States It has been seriously said, verbally if not in print, that penicillin is the final answer, to be shortly effective in eradicating syphilis altogether or relegating it to the minor status of typhoid fever As yet, however, the epidemiologist is unprepared to accept this glowing optimism He must examine the rest of the evidence

In the United States, *methods to increase the availability of diagnostic and treatment facilities* have been outstandingly successful, and it is for this phase of the programme that most of the syphilis control dollar has been spent It is now possible for an infected person anywhere in the United States to receive comparatively

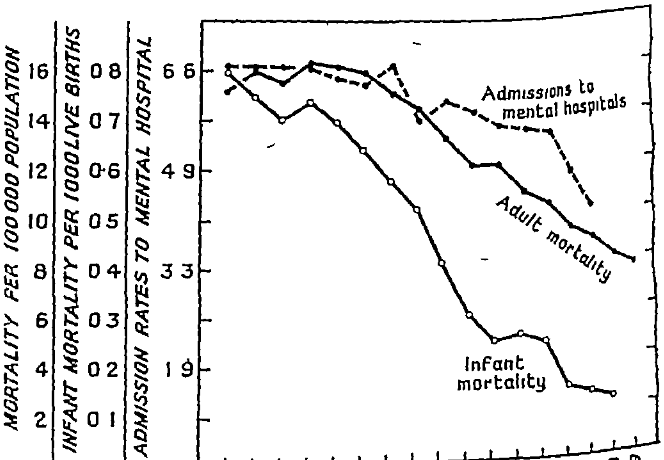

Fig 21—Comparison of adult and infant mortality from syphilis and of admissions to mental hospitals for syphilitic psychosis, in the United States 1933–49 (adapted from U.S Public Health Service 1947 1950)

These curves are adjusted in scale to an identical 100% starting point The declines may be interpreted as a by product of the syphilis control programme, and as the result of discovery of late syphilis rather than early syphilis, with prevention of complications and death by treatment developed through further medical research, is a more promising approach.

INTRAMEDULLARY NAILING IN RECENT FRACTURES OF THE FEMORAL SHAFT

G C LLOYD-ROBERTS
M.B Camb , F.R C.S
SENIOR REGISTRAR, ORTHOPÆDIC DEPARTMENT,
ST PETER'S HOSPITAL, CHERTSEY

ON the Continent intramedullary nailing is a well-recognised and widely practised method of treatment for fractures of the femoral shaft, and a copious literature has accumulated. Very few reports, however, have appeared in England. Fraenkel (1948) described cases he observed while on a visit to Kiel, Chance (1949) reviewed a personal series in a paper read before the British Orthopædic Association, and McKee (1948) reported unfavourably on his experience of three cases in which he had used trifin nails. Watson Jones et al. (1950) in a long article in the *Journal of Bone and Joint Surgery* have reviewed the difficulties and complications of this method. It therefore seems advisable to review the results obtained in twenty cases at this hospital.

It must be emphasised that intramedullary nailing presents no new principle in the treatment of fractures. Hey Groves (1918–19) applied the technique experimentally, Lambotte (1913) treated fractures of the clavicle in this manner, and Lambrinudi (1940) the ulna. It has an established position in certain fractures of the metacarpals and phalanges. For fractures of the shaft of the femur it is the logical sequel to the acceptance of Smith Petersen's intramedullary fixation of fractures of the femoral neck. Long Smith-Petersen nails within the medullary cavity of the shaft were used in the treatment of subtrochanteric fractures by B H Burns in 1938 and G K McKee in 1940 (personal communications).

Küntscher (1940) must receive full credit for establishing the method. His contribution delivered before the Berlin Surgical Congress although for the most part coldly received, was followed by a renewal of interest in the principle, and consequently Böhler's (1948) monograph describes in detail the experiences of the Viennese school and includes a considerable bibliography.

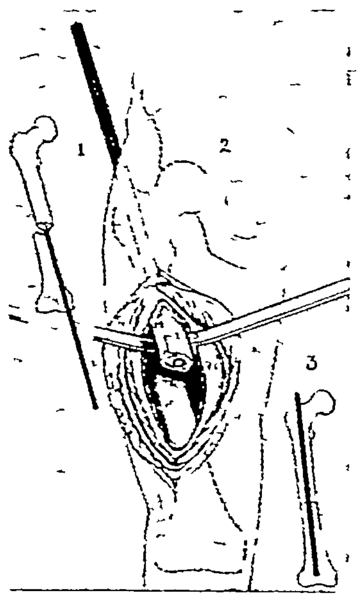
In the United States the method, though gaining in popularity, cannot yet be described as the standard treatment for fractures of the shaft of the femur. Several notable papers have, however, been published, including Haebler's (1949) review of 118 cases.

MATERIAL

Experience at this hospital of intramedullary nailing of the femoral shaft comprises 37 cases, but in 17 the operation was performed for mal union, non union, or limb shortening. Only the remaining 20 cases, in which nailing was used as the primary definitive treatment, are considered here. The length of time that elapsed between fracture and operation was a matter of hours in 7 cases, and days in 9. The remaining 4 cases were operated on within two weeks of injury. In 1 case the fracture was compound, and in 3 others it was complicated by fractures of the bones of the lower leg on the same side. The ages of the patients ranged from 17 to 85.

OPERATION

The method used involves exposure of the fracture and insertion of the nail under direct vision. We have not tried the closed method which entails manipulative reduction under X-ray control and the passage of the nail from the trochanteric region of the femur by indirect means. We prefer to expose the fracture and pass the nail under direct vision (see figure), feeling that the theoretical advantages of the closed method are outweighed by the longer time it takes and by some inevitable loss of precision. Furthermore Burns early experienced difficulties in finding the precise spot on the neck of the femur for introduction of the nail from above. This led to his return in 1943 to the older method of Hey Groves in which the nail is inserted through the fracture site. The closed method is, however, more in favour among Continental surgeons who have been denied until recently the advantages of antibiotics.



Intramedullary nailing 1 nail about to be inserted into proximal fragment of femur 2, nail driven through proximal fragment 3 nail driven into distal fragment.

The figure illustrates the principle of the operation but a few points require special emphasis.

Before the operation is begun, the distance from the tip of the great trochanter to the knee joint is measured on the normal side. U-shaped nails of various diameters are selected measuring 4 cm less than this measurement. The fracture is exposed by an anterolateral approach in most cases, but fractures of the subtrochanteric region are more easily dealt with through a lateral approach. The incision should extend more generously over the proximal fragment than over the distal. When the fracture has been exposed, the proximal fragment must be delivered into the wound so that the medullary cavity presents at the surface. A nail is selected whose diameter fits snugly the medullary cavity at its narrowest point. The nail is hammered upwards through the proximal fragment until it is felt to penetrate the cortex of the basal part of the neck of the femur medial to the great trochanter. At this stage it will be an advantage to adduct the limb as far as possible before driving the nail into the subcutaneous tissue of the buttock, so that other wars) in what can only be described as a fresh epidemic of syphilis in Europe and the United States From the end of World War II, it is yet far too soon, probably at least by a decade, to determine whether the presently occurring decline represents only a return of population stability, or a continuing acceleration due to the increasing application of control measures, especially penicillin

The 1910–50 trend of incidence of syphilis is certainly influenced by the factors operative before 1910, especially slow improvement in socio economic conditions, and fluctuations in population stability The gradual decline probably initiated in the mid 19th century has apparently been accelerated by modern public health control measures But this acceleration is not yet sufficiently significant (unless in Scandinavia) to promise eventual complete control in any country, nor to set a time limit within which that desired goal may be reached Certainly it is not enough to justify complacent relaxation of effort or a decrease in the expenditure of public funds Premature satisfaction with accomplishment is dangerous

In one direction, the expenditure of additional money seems essential—i e , the gathering of reliable information on the incidence and prevalence of syphilis in various countries The discussion of this paper makes abundantly clear the difficulty of estimating the effect of a control programme or of any of its components for lack of such data For individual countries and for the World Health Organisation, Guthe and Hume emphasise this in saying " One of the main needs is the establishment of uniform reporting procedures and nomenclature throughout the world Reports should be available currently and analysis of the reports should also proceed on a reasonably current basis in order to provide useful information to the nations of the world" (Vonderlehr 1939) The mathematician finds it impossible to solve a problem unless provided with the basic figures

Will a Control Programme based on Present Knowledge be Effective in Global Eradication?

In a global sense, certain infections may be eradicated entirely in one country while they flourish in another With syphilis, as with tuberculosis, this is improbable Improved transportation methods facilitate population exchange While endemic areas of syphilis exist anywhere in the world, it is unlikely that any country will locally so reduce the importance of the infection as to avoid a few smouldering endemic foci of its own, and a new epidemic with a new cause of population instability It is, therefore, pertinent to inquire into the possible global eradication of syphilis with the means at present to hand

The cost of syphilis control, on the basis of United States and Scandinavian programmes, is sufficiently high as to make it difficult to envisage their applicability in some densely populated but less prosperous countries which presently have a high rate of incidence and prevalence—e g , China, India If this be true—if in turn the continued existence of the infection in one country constitutes a potential public health danger to another, no matter how successful the latter may have been in stable peace time years—how best can we approach the problem on a global basis?

MEDICAL RESEARCH IN THE CONTROL OF SYPHILIS

I have deliberately left till last any consideration of an all important method of syphilis control, *medical research* In 1939 there was presented in the United States a symposium on unsolved problems as to syphilis (Vonderlehr 1939, Moore 1939, Eagle 1939) The questions posed then remain largely unanswered 11 years later Some of the many gaps in knowledge have not only fundamental biological but also very practical epidemiological importance Virulent *T pallidum* has never been successfully grown on artificial media This is the very cornerstone of further progress Until it is successfully accomplished, we shall remain ignorant of the chemistry of the organism, its growth requirements, its life-cycle, and the possible infectivity of non spiral forms, the explanation for its extraordinary predilection for certain tissues in man, the factors underlying immunity and allergy, the development of a genuinely specific diagnostic test, and the fascinating possibility of mass immunisation.

The solution of these and other practical problems depends upon financial support of medical research, with a large proportion of the syphilis control dollar for this purpose than has heretofore been available even in the United States Emphasis should be on fundamental rather than on applied investigation, since on the unsolved fundamental problems outlined above depends the development of effective immunisation.

If immunisation proved to be possible, then—and perhaps not until then—will there be surely within grasp a financially feasible method of global relegation of the great pox to the present level of oblivion now achieved for smallpox

SUMMARY AND CONCLUSIONS

1 The evaluation of a public health programme for the control of syphilis depends on accurate epidemiological figures as to morbidity and mortality, from which trends may be estimated

Reliable information on these points is not available in any country before the mid 19th century From about 1865 to 1940, it may be had for civilian population groups from Scandinavia only , but it is available, with varying degrees of validity, for military population groups from several countries of Western Europe and the United States After 1940, data as to trends among civilians begin to accumulate in the United States

2 Since the scientific discoveries of 1905–10, the public health control of syphilis has been potentially possible. Trends from 1910 to the present may therefore be compared with those in the roughly equal time-period 1865–1910, when, for lack of this knowledge, control efforts were largely futile

3 In both of these periods, pre 1910 and post 1910, there can be no doubt that war or internal unrest is accompanied, in any country involved, by an increase in morbidity followed by a post war decrease

4 Military data strongly suggest that from 1865 to 1910 there was a decline in the incidence of syphilis in most countries of Western Europe and in the United States

5 The factors possibly contributing to this decline are (*a*) a natural phenomenon of infectious disease, with modifications of the host parasite relationship , (*b*) a general improvement in socio economic conditions in Western civilisation , and (*c*) relative population stability after a long period of instability

6 These same long term influences have also operated since 1910

7 Since 1910, there has been a further decline in the incidence of syphilis in Western Europe and the United States , and at a probably accelerated rate The acceleration may be attributed to modern public health control measures, especially the application of effective treatment to millions of infected persons, and of programmes designed to increase the number of such persons brought to treatment As a by effect of these efforts, mortality has probably declined more rapidly than morbidity

8 The possible effect of penicillin in further accelerating the decline in incidence cannot be measured for at least another decade

9 The present decline is not yet sufficient (unless in Scandinavia) to promise eventual complete control in any country, to permit the relaxation of control efforts, or to set a time limit on achievement of the desired goal

10 Global control is unlikely with the methods at present available Mass immunisation, if this can be

eveloped through further medical research, is a more romising approach

MEDICAL RESEARCH IN THE CONTROL OF SYPHILIS

I have deliberately left till last any consideration of an all important method of syphilis control, *medical research* In 1939 there was presented in the United States a symposium on unsolved problems as to syphilis (Vonderlehr 1939, Moore 1939, Eagle 1939) The questions posed then remain largely unanswered 11 years later Some of the many gaps in knowledge have not only fundamental biological but also very practical epidemiological importance Virulent *T pallidum* has never been successfully grown on artificial media This is the very cornerstone of further progress Until it is successfully accomplished, we shall remain ignorant of the chemistry of the organism, its growth requirements, its life-cycle, and the possible infectivity of non spiral forms, the explanation for its extraordinary predilection for certain tissues in man, the factors underlying immunity and allergy, the development of a genuinely specific diagnostic test, and the fascinating possibility of mass immunisation.

The solution of these and other practical problems depends upon financial support of medical research, with a large proportion of the syphilis control dollar for this purpose than has heretofore been available, even in the United States Emphasis should be on fundamental rather than on applied investigation, since on the unsolved fundamental problems outlined above depends the development of effective immunisation

If immunisation proved to be possible, then—and perhaps not until then—will there be surely within grasp a financially feasible method of global relegation of the great pox to the present level of oblivion now achieved for smallpox

SUMMARY AND CONCLUSIONS

1 The evaluation of a public health programme for the control of syphilis depends on accurate epidemiological figures as to morbidity and mortality, from which trends may be estimated

Reliable information on these points is not available in any country before the mid 19th century From about 1865 to 1940, it may be had for civilian population groups from Scandinavia only , but it is available, with varying degrees of validity, for military population groups from several countries of Western Europe and the United States After 1940, data as to trends among civilians begin to accumulate in the United States

2 Since the scientific discoveries of 1905–10, the public health control of syphilis has been potentially possible. Trends from 1910 to the present may therefore be compared with those in the roughly equal time period 1865–1910, when, for lack of this knowledge, control efforts were largely futile

3 In both of these periods, pre 1910 and post 1910, there can be no doubt that war or internal unrest is accompanied, in any country involved, by an increase in morbidity followed by a post war decrease

4 Military data strongly suggest that from 1865 to 1910 there was a decline in the incidence of syphilis in most countries of Western Europe and in the United States

5 The factors possibly contributing to this decline are (*a*) a natural phenomenon of infectious disease, with modifications of the host parasite relationship , (*b*) a general improvement in socio economic conditions in Western civilisation , and (*c*) relative population stability after a long period of instability

6 These same long term influences have also operated since 1910

7 Since 1910, there has been a further decline in the incidence of syphilis in Western Europe and the United States , and at a probably accelerated rate The acceleration may be attributed to modern public health control measures, especially the application of effective treatment to millions of infected persons, and of programmes designed to increase the number of such persons brought to treatment As a by effect of these efforts, mortality has probably declined more rapidly than morbidity

8 The possible effect of penicillin in further accelerating the decline in incidence cannot be measured for at least another decade

9 The present decline is not yet sufficient (unless in Scandinavia) to promise eventual complete control in any country, to permit the relaxation of control efforts, or to set a time limit on achievement of the desired goal.

10 Global control is unlikely with the methods at present available Mass immunisation, if this can be

in nailed fractures produces little callus between the cortices involved in the fracture Union depends mainly on callus laid down peripherally This was a constant finding in our series It has been suggested that pressure of the nail in the medullary cavity is responsible (Fitts et al. 1949)

As the time of "bony union" I have therefore taken the point at which unprotected weight bearing without sticks or splintage is allowed This corresponds functionally to the stage of consolidation in fractures treated by closed methods

The average time between injury and the removal of all protection was 17 2 weeks This compares favourably with the 23 weeks required to reach the same stage in a group of femoral fractures treated without internal fixation in this hospital

The absence of late bending at the fracture site in any case taking full weight confirms that functional consolidation had indeed taken place

Complications

The 1 death from causes unassociated with the operation has been mentioned. There were no cases of septic bone, non-union, or fat emboli Superficial sepsis occurred in the buttock wound in 1 case this is potentially a weak point in the technique and has been mentioned above

Three cases require particular consideration

Case 3 —A man with a fracture of the upper third of the femur was found to have bent his nail during the period of partial weight-bearing. He was one of the early cases (1945), and it is now evident that the nail used was too short The angulation of the femur is not gross, and when the patient was last seen five years later he had 1 in. of shortening but a full range of movement. He is following his pre war trade as a bricklayer

Case 4 —A man was discharged from hospital bearing partial weight six weeks after nailing of a transverse middle third fracture Next day he fell on to a concrete floor and bent his nail at the site of fracture He was readmitted, and true alignment was restored by traction. This was possible because the distal fragment could be moved on the pin in the splayed-out lower end of the bone The final result is excellent, but the pin will probably have to be left in situ.

Case 5 —An uncoöperative schizophrenic had an oblique fracture at the junction of the middle and lower thirds of the femur After operation he could not be restrained, and as early as two weeks later he was walking round his room without any support The site and obliquity of the fracture, coupled with early unprotected weight bearing have led to early bony union with 20° of angulation at the fracture site and a secondary genu valgum. Further surgery may be necessary

In summary, therefore the complications which have arisen have, apart from one exceptional case, had no influence upon the final result

REMOVAL OF NAIL

The nail should be removed when firm consolidation has taken place This can be very easily done through a small incision over the buttock and with an extractor which resembles a crochet hook and fits the slot made in the end of the nail for this purpose The nail is removed because a bursa often forms round the protruding tip and causes pain when the patient sits down, and because the permanent retention of so large a piece of metal within the medulla may have its own dangers

SUMMARY

Intramedullary nailing in 20 cases of fracture of the femoral shaft is reviewed The operation and its indications are described Return of function and bony union are good. A few complications are described

I am very grateful to Mr B H. Burns and Mr R H. Young under whose care the patients were treated at St Peter's Hospital, Chertsey (Botleys Park), for permission to review their cases, and for their assistance in the preparation of this report My thanks are also due to Miss Zita Stead for the illustration.

DIPHTHERIA ANTITOXIN IN CORD-BLOOD

SURVEY OF SAMPLES FROM 15 AREAS OF BRITISH ISLES

MOLLIE BARR

IN a study of factors involved in the active immunisation of young babies against diphtheria Barr et al. (1950) found that, when the level of passive maternally conferred antitoxin in babies was below 0 04 unit per ml at the time of the first injection of prophylactic (0 5 ml of A.P.T), there was no interference with active immunisation, whereas titres of 0·1 unit per ml, or more, caused interference with the first dose of A.P.T

Barr et al (1949) showed that it was possible to calculate from the antitoxic titres of the cord-blood, the age at which any baby could be injected with prophylactic without interference from passive antitoxin Barr et al. (1950) calculated that over 80% of a population of 200 babies born in South-East London would be satisfactorily immunised if they received the first dose of 0 5 ml. of A.P.T at the age of 3 months They suggested that antitoxin titrations on a limited number of cord-blood samples from different districts would give a good idea of the immunity state of the newborn, and that methods of immunisation could be derived therefrom which would be most satisfactory for most of the babies

This paper gives analyses of values of cord-blood samples from fifteen areas of the British Isles—Aberdeen, Birmingham, Cardiff, Castleford, Cork, Coventry, Dumfries, Glasgow, Leeds, three districts of London, Rochdale, Stratford on-Avon, and West Bromwich The statistical analyses were done by one of us (M B) The values recorded are those of a relatively large age group, most of the mothers being aged 20–35, but some being older or younger They cannot be regarded as a fair sample of the general population, because most of the samples were obtained from urban areas The figures give a picture of the immunity state at present, and may change considerably in future years according to the trend of immunisation and the presence or absence of epidemics

The techniques adopted for taking the cord-blood samples and estimating the antitoxin levels were those described by Barr et al. (1949) They found that the distributions of values of 100 samples from each of two socially similar districts of South-East London were not significantly different In the present investigation of cord-blood from different districts a sample of 100 has therefore been studied, although from one large industrial town two consecutive samples of 100 were compared, and confirmed that the number tested constituted an adequate statistical sample

The results of this comparison are shown in table I the antitoxic values being arranged in five groups I the second wound made over the emerging point of the nail will be placed as far laterally as possible The proximal end of the nail is then driven out through the skin until the distal end is flush with the level of the fracture (The use of a second incision and the passage of the nail through the skin is a theoretically weak point in the technique We have had a minor complication attributable to this) The fracture is now reduced under direct vision and held in the reduced position while the nail is driven across the fracture into the distal fragment to its full extent The aim should be to leave as small a length of the nail as possible projecting above the trochanter The full introduction of the nail will be found simpler if an assistant applies traction to the leg while the nail is being hammered into position The incisions are both closed, and the patient is returned to bed without any other form of fixation whatever

INDICATIONS

Although the present series is small, we feel that we now have sufficient experience of the method to differentiate between those cases in which intramedullary nailing may be used with benefit and those in which it is contra indicated

We have come to regard nailing as the method of choice for fractures between and including the subtrochanteric region and the junction of the middle and lower thirds of the shaft, unless they are extensively comminuted or other local or general factors preclude operation Fractures of the lower third cannot be effectively maintained in the position obtained at operation without additional external fixation or traction This, by preventing early unhampered movement of both the patient and his limb, neutralises the advantages of intramedullary nailing

Failure to maintain reduction in low fractures is due to two factors (1) the short length of nail that can be passed distal to the fracture cannot prevent angulation and may lose contact with the distal fragment if any upward riding of the nail as a whole takes place, and (2) the disproportion between the diameter of the nail and the flared out medullary cavity prevents firm contact between the nail and the cortical bone in a circumferential plane at the level of the fracture

The danger of causing severe damage to the bone by secondary splitting due to the impact of the nail has discouraged us from using the method in comminuted fractures Further, comminution of the proximal fragment prevents the elevation of this fragment into the wound—an essential step in the operation

In addition to the broad indications outlined above there are two types of case in which we feel that nailing has a particular application

(1) In fractures of the femoral shaft complicated by fracture of the tibia and fibula on the same side, where the operation is combined with internal fixation of the tibial fracture We believe that this notoriously difficult problem is best treated in this way An obstinately stiff knee need not be the price the patient must pay for a reconstructed limb, his postoperative régime does not involve restriction of movement

Case 1 —A boy, aged 19, had a motor accident and sustained a transverse fracture of the middle third of his right femur and a transverse fracture of his right tibia, with a large butterfly third fragment Operation three hours later consisted in intramedullary nailing of the femur and plating of the tibia No further fixation was considered necessary at any time Six weeks later the patient was up and about on crutches, having control of the limb and knee flexion to 70° He was accordingly discharged to his home and attended as an outpatient At nineteen weeks he had a full range of knee movement and was walking without protection, his fractures being in anatomical position.

(2) By removing the necessity to restrict movement, and by reducing the period of recumbency, intramedullary nailing minimises the problems which arise in treating old people

Case 2 —A woman, aged 85, fell from her bed two months after a nailing operation for a fractured neck of femur and sustained a subtrochanteric fracture through the level at which the pin had been inserted Five days later intramedullary nailing was done and the Smith Petersen nail was removed The transcervical fracture was stable enough to require no further treatment The postoperative course was uneventful, and the patient was allowed up in a chair two weeks after the operation At four weeks she got about with two sticks, and at ten weeks she walked without protection. Six months after the operation the fracture was soundly united and she walked well with one stick. In spite of her two operations she still retained 120° of knee flexion—10° less than on her normal side

RESULTS

Of the 20 patients under review, 1 died six weeks after the operation, from cerebral hæmorrhage, 3 cases are too recent for assessment, and 2 in subjects of Paget's disease are also excluded There remain 14 cases for analysis

Our earliest case treated in this way has now been followed for more than six years, 5 for more than three years, and 6 for a year or more Results are reviewed in terms of functional restoration, bony union, and complications

Return of Function

The postoperative régime allows the patient to move about freely in bed from the start It is our impression that this not only reduces his discomfort but also favours rapid return of mental well being Nursing is much easier and the risk of deep venous thrombosis is less.

We allow the patients to walk with crutches without weight bearing when the wound is healed and when they can lift the leg off the bed The average delay before these two criteria are satisfied has been 3.3 weeks This is an important step in that it allows more purposeful active movement of the knee joint and thus reduces the extent and duration of the reactionary œdema

Partial weight bearing is encouraged at a time which depends on various factors Local conditions peculiar to the fracture—i e , its degree of obliquity and level—and associated injuries, especially of the leg bones on the same side, will influence this decision Especially favourable cases—i e , transverse fractures of the middle third—have taken weight at four weeks and rapidly graduated to unprotected weight bearing at six weeks In spite of this early weight bearing we have not seen displacement in these transverse fractures This is probably due to the fact that the nail obtains its greatest grip at this level On the other hand, a patient with an ipsolateral tibial fracture did not bear weight until eighteen weeks had elapsed

The average time taken to achieve partial weight bearing was 8.5 weeks, this is the stage at which most of these patients are discharged from hospital

The restoration of function to the knee joint, always of moment in this injury, has been studied in some detail. When they were discharged from medical supervision 11 patients had achieved full flexion at the knee Of the remainder, 2 are untraced and 1 has only 90° of flexion

Although these end results are gratifying, I want to emphasise again the speed with which function is re established in these cases Early weight bearing allows early discharge from hospital and rapid rehabilitation, and this is, we believe, achieved without prejudice to the final result

Bony Union

The stability afforded by a well fitting nail prevents assessment of union by traditional clinical methods Radiography is also of doubtful value, because union in nailed fractures produces little callus between the cortices involved in the fracture Union depends mainly on callus laid down peripherally This was a constant finding in our series. It has been suggested that pressure of the nail in the medullary cavity is responsible (Fitts et al. 1949)

As the time of "bony union" I have therefore taken the point at which unprotected weight bearing without sticks or splintage is allowed This corresponds functionally to the stage of consolidation in fractures treated by closed methods

The average time between injury and the removal of all protection was 17 2 weeks This compares favourably with the 23 weeks required to reach the same stage in a group of femoral fractures treated without internal fixation in this hospital

The absence of late bending at the fracture site in any case taking full weight confirms that functional consolidation had indeed taken place

Complications

The 1 death from causes unassociated with the operation has been mentioned There were no cases of septic bone, non-union, or fat emboli Superficial sepsis occurred in the buttock wound in 1 case this is potentially a weak point in the technique and has been mentioned above

Three cases require particular consideration

Case 3 —A man with a fracture of the upper third of the femur was found to have bent his nail during the period of partial weight-bearing He was one of the early cases (1945), and it is now evident that the nail used was too short The angulation of the femur is not gross, and when the patient was last seen five years later he had 1 in. of shortening but a full range of movement He is following his pre war trade as a bricklayer

Case 4 —A man was discharged from hospital bearing partial weight six weeks after nailing of a transverse middle third fracture Next day he fell on to a concrete floor and bent his nail at the site of fracture He was readmitted, and true alignment was restored by traction. This was possible because the distal fragment could be moved on the pin in the splayed-out lower end of the bone The final result is excellent, but the pin will probably have to be left in situ.

Case 5 —An uncoöperative schizophrenic had an oblique fracture at the junction of the middle and lower thirds of the femur After operation he could not be restrained, and as early as two weeks later he was walking round his room without any support The site and obliquity of the fracture, coupled with early unprotected weight bearing, have led to early bony union with 20° of angulation at the fracture site and a secondary genu valgum. Further surgery may be necessary

In summary, therefore, the complications which have arisen have, apart from one exceptional case, had no influence upon the final result

REMOVAL OF NAIL

The nail should be removed when firm consolidation has taken place This can be very easily done through a small incision over the buttock and with an extractor which resembles a crochet hook and fits the slot made in the end of the nail for this purpose The nail is removed because a bursa often forms round the protruding tip and causes pain when the patient sits down, and because the permanent retention of so large a piece of metal within the medulla may have its own dangers

SUMMARY

Intramedullary nailing in 20 cases of fracture of the femoral shaft is reviewed The operation and its indications are described Return of function and bony union are good A few complications are described

I am very grateful to Mr B H. Burns and Mr R H. Young, under whose care the patients were treated at St Peter's Hospital, Chertsey (Botleys Park) for permission to review their cases, and for their assistance in the preparation of this report My thanks are also due to Miss Zita Stead for the illustration.

In a study of factors involved in the active immunisation of young babies against diphtheria Barr et al. (1950) found that, when the level of passive maternally conferred antitoxin in babies was below 0 04 unit per ml at the time of the first injection of prophylactic (0 5 ml of A.P T), there was no interference with active immunisation, whereas titres of 0·1 unit per ml., or more, caused interference with the first dose of A.P T

Barr et al. (1949) showed that it was possible to calculate from the antitoxic titres of the cord-blood, the age at which any baby could be injected with prophylactic without interference from passive antitoxin Barr et al. (1950) calculated that over 80% of a population of 200 babies born in South East London would be satisfactorily immunised if they received the first dose of 0·5 ml. of A.P T at the age of 3 months They suggested that antitoxin titrations on a limited number of cord-blood samples from different districts would give a good idea of the immunity state of the newborn, and that methods of immunisation could be derived therefrom which would be most satisfactory for most of the babies

This paper gives analyses of values of cord-blood samples from fifteen areas of the British Isles—Aberdeen, Birmingham, Cardiff, Castleford, Cork, Coventry, Dumfries, Glasgow, Leeds, three districts of London, Rochdale, Stratford on-Avon, and West Bromwich The statistical analyses were done by one of us (M B) The values recorded are those of a relatively large age group, most of the mothers being aged 20–35, but some being older or younger They cannot be regarded as a fair sample of the general population, because most of the samples were obtained from urban areas The figures give a picture of the immunity state at present, and may change considerably in future years according to the trend of immunisation and the presence or absence of epidemics

The techniques adopted for taking the cord blood samples and estimating the antitoxin levels were those described by Barr et al (1949) They found that the distributions of values of 100 samples from each of two socially similar districts of South East London were not significantly different In the present investigation of cord blood from different districts a sample of 100 has therefore been studied, although from one large industrial town two consecutive samples of 100 were compared, and confirmed that the number tested constituted an adequate statistical sample

The results of this comparison are shown in table I the antitoxic values being arranged in five groups I

TABLE I—COMPARISON OF DISTRIBUTION OF ANTITOXIC VALUES IN TWO CONSECUTIVE SERIES EACH OF 100 CORD BLOOD SAMPLES FROM THE SAME TOWN

Antitoxic values (units per ml)	No of cord blood samples		
	Series 1	Series 2	Total
Under 0 001	41	32	73
0 001 0 002 0 004	9	11	20
0 01 0 02, 0 04	17	19	36
0 1, 0 2 0 5	23	30	53
1 0, 2 0, 5 0	10	8	18
Total	100	100	200

$\chi^2 = 2\ 568$ 4 D F P = 0 635

will be seen that there was no significant difference in distribution between the two series, and a high value of P (0 635) was obtained It was therefore concluded that a sample of 100 is adequate for statistical comparisons

DISTRIBUTION OF VALUES

Table II shows in detail the distribution of values from all fifteen districts investigated These have been arranged in order according to the numbers with no detectable antitoxin, and the districts have been named from A to O to preserve anonymity The numbers with less than 0 001 unit per ml range from 59 in district A to 21 in district O, with an average of 34 8 The differences between the numbers with and without detectable antitoxin are highly significant ($\chi^2 = 64\ 29$ 14 D F P = < 0 001) A comparison of the general distribution of values, arranged in groups as indicated by the brackets in column 1 of table II, shows that the differences are highly significant (see foot of table II) The chief points of difference lie in the numbers with no detectable antitoxin, and to a lesser degree in those with over 0 1 unit per ml District N provided an abnormally large number of high values, 20% being 1 unit or higher 11 samples from M and 10 from D contained 1 unit or more, but only 2 samples of such value were obtained from district I Barr (1950) has already shown that the number of samples with no detectable antitoxin in any population may give no indication of the mean value or the scatter of the remainder Table II shows that the number of high values, over 0 5 or 1 unit, is unrelated to the values of the rest of the population It is clear that some difficulty would be encountered in formulating a simple scheme of immunisation for district N, owing to the large scatter of values and the number of high titres found in this population It should be noted that the only sample with a value of over 20 units was obtained from that district Table II shows that values of 10 units per ml or higher are rare, only 5 of the 1500 samples (0·33%) reached or exceeded this figure Slightly lower values would have been expected had the blood samples been taken from the mothers, because Barr et al (1949) found that the antitoxic content of cord blood was usually appreciably higher and might be double that of the mother's blood taken during labour This observation has recently been confirmed by Murray et al (1950), who compared the staphylococcal antitoxic titres of serum from cord-blood, and mothers' and infants' blood

The main peaking in value in the distributions shown in table II occurs over the range 0 04, 0 1, 0 2, 0 5 unit, but in several cases there is a suggestion of a lower peak, usually at 0 004 unit per ml , this is especially evident in districts D and M

TABLE III—DISTRIBUTION OF ANTITOXIC VALUES AMONG SERIES OF 100 CORD BLOOD SAMPLES FROM FIVE INDUSTRIAL TOWNS

Antitoxic value (unit per ml)	No of samples from district					Total
	C	D	E	H	M	
Under 0 001	42	41	37	34	25	179
0 01–0 004	10	9	10	8	10	47
0 01–0 04	17	17	16	13	15	78
0 1 0 2	19	14	21	27	27	108
0 5 and over	12	19	16	18	23	88
Total	100	100	100	100	100	500

$\chi^2 = 15\ 685$ 10 D F P = 0 48

COMPARISON OF VALUES FROM VARIOUS AREAS

As we have already stated, Barr et al (1949) found that the distributions of values in samples from two districts of South East London were not significantly different A third district of London has now been investigated, 100 samples from Queen Charlotte's Hospital being examined, and a comparison has been made between these three series of samples The differences found were not significant ($\chi^2 = 8\ 005$ 4 D F P = 0 093), the value of P was considerably lower however than that obtained by Barr et al for the South East London samples The chief difference between the districts lay in the smaller number of low values (under 0 01) in the South East London series

A comparison has been made between five industrial towns in the provinces—Birmingham, Coventry, Leeds, Rochdale, and West Bromwich—and the results are

TABLE II—DISTRIBUTION OF ANTITOXIC VALUES AMONG SERIES OF 100 CORD-BLOOD SAMPLES TAKEN FROM 15 AREAS OF BRITISH ISLES

26	96	98	98	95	96	98	98	98	99	98	96	93	96	89	97	1445 (*96·3%*)
34	100	99	99	99	99	100	99	100	100	100	100	97	99	95	100	1486 (*99·1%*)

shown in table III. These districts are represented as C, D, E, H, and M in table II, but the sequence is not as stated above. There is no significant difference between the distributions of values of blood samples from these areas, and the differences between districts C and M are not significant when compared alone, except for the numbers with and without detectable antitoxin.

Comparisons have also been made between samples from the London area and from these same five provincial towns, and table IV shows that the differences in distribution are highly significant. The analysis shows that the number of samples with less than 0·01 unit per ml is below expectation in the London series, the number between 0·01 and 0·2 exceeds expectation, while the number of high value samples, above 0·5 unit, is approximately equal to the expected number. The differences between the distributions are even greater if the West London samples (Queen Charlotte's Hospital) are excluded for the latter are statistically comparable with the provincial samples (χ^2 = 4·019 4 D.F P = 0·41).

It is unfortunately impossible to make any comparison between strictly rural and urban districts, because many of the towns included in the survey receive patients from outlying rural areas.

TABLE IV—COMPARISON OF DISTRIBUTION OF ANTITOXIC VALUES AMONG CORD BLOOD SAMPLES FROM LONDON AND FIVE INDUSTRIAL TOWNS IN THE PROVINCES

Antitoxic value (unit per ml.)	Percentage of samples from		Total no of samples
	London	Industrial towns	
Under 0·001	28·0	35·8	263
0·001–0·004	5·0	9·4	62
0·01–0·04	22·0	15·6	144
0·1–0·2	29·0	21·6	195
0·5 and over	16·0	17·6	136
Total	300	500	800

χ^2 = 16·914 4 D F P = <0·01

Possibly differences which may have existed in the past between the antitoxic values of people from rural and urban districts are now reduced to some extent because of the greater movements of the population in recent times. Of a small number of samples received from a rural area, however and not included in table II few contained any detectable antitoxin.

EFFECT OF EPIDEMICS

Certain towns included in this survey have experienced severe epidemics within the last twenty years. The distribution of antitoxic values from these areas does not differ from those of similar towns which have not experienced such epidemics. This may possibly be explained by the long lapse of time between the epidemics and the sampling of the population. It is possible that many of the mothers were not then residing in the area affected by the epidemic. The percentage of mothers in each of two such towns, who stated that they had had diphtheria, was less than half those in 6 out of 8 other districts returning information. There is no reason to suppose that the information from these towns was less reliable than that from the other 8. There are insufficient figures from immunised mothers for any conclusions to be drawn as to the relative success of methods of immunisation in different districts. The wide age group covered would necessitate the examination of very large numbers of samples.

AGE AT WHICH IMMUNISATION COULD BE STARTED

It has already been shown (Barr 1950) that the numbers of babies born in Coventry and Southwark (S.E. London) with antitoxic values below the Schick level were significantly different, the numbers in these areas that could be satisfactorily immunised at the age of 3 months, however, were not significantly different.

Table V gives the approximate Schick-positive rates of the mothers in each of the fifteen districts of this survey. For this purpose all with cord blood values under 0·004 unit per ml. have been recorded as Schick-positive, and those with values of 0·004 unit or higher as Schick-negative. The figures therefore give only a fair approximation to the result which would have been obtained had the Schick test actually been carried out; probably they provide a slightly lower estimate, in view of the higher titre of cord blood. Very considerable differences, which are clearly highly significant, exist between the approximate Schick-positive rates in the fifteen districts (χ^2 = 73·718 14 D.F P = <0·001). The figures range from 23 in district O to 62 in district A, with an average of 37·6. It will be seen that the order of the figures from A to O is roughly, but not exactly, the same as that in table II, where the number of samples with no detectable antitoxin is given.

Table V also shows the numbers of babies that could be satisfactorily immunised if they received their first dose of A.P.T. at birth and at the age of 3, 6, and 8 months; these figures were obtained by calculation and represent the numbers whose level of maternally conferred antitoxin would have fallen below 0·04 unit per ml. at these ages. Very considerable differences exist between the numbers that could be immunised at birth, and the average number is just over 50% for the 1500 samples. At the age of 3 months the differences are greatly reduced, ranging from 70 in district O to 93 in district A; these differences are highly significant (χ^2 = 38·097 14 D.F P = <0·001). A study of the table shows that the greatest deviation from the mean is provided by district N, and, if this figure is omitted from the analysis, the value of P becomes 0·05. At the age of 6 months 96·3% of the babies could be successfully immunised (though only 89% in district N), and little is gained by further delaying the first dose of prophylactic until the age of 8 months, officially recommended at present.

It is abundantly clear from table V that, as noted before (Barr 1950), little useful information as to when immunisation can be started in a population is provided

TABLE I—COMPARISON OF DISTRIBUTION OF ANTITOXIC VALUES IN TWO CONSECUTIVE SERIES EACH OF 100 CORD BLOOD SAMPLES FROM THE SAME TOWN

Antitoxic values (units per ml)	No of cord blood samples		
	Series 1	Series 2	Total
Under 0 001	41	32	73
0 001 0 002 0 004	9	11	20
0 01, 0 02 0 04	17	19	36
0 1 0 2, 0 5	23	30	53
1 0, 2 0, 5 0	10	8	18
Total	100	100	200

$\chi^2 = 2\ 568 \quad 4$ D F $\quad P = 0\ 635$

will be seen that there was no significant difference in distribution between the two series, and a high value of P (0 635) was obtained It was therefore concluded that a sample of 100 is adequate for statistical comparisons

DISTRIBUTION OF VALUES

Table II shows in detail the distribution of values from all fifteen districts investigated These have been arranged in order according to the numbers with no detectable antitoxin, and the districts have been named from A to O to preserve anonymity The numbers with less than 0 001 unit per ml range from 59 in district A to 21 in district O, with an average of 34 8 The differences between the numbers with and without detectable antitoxin are highly significant ($\chi^2 = 64\ 29$ 14 D F $P = < 0\ 001$) A comparison of the general distribution of values, arranged in groups as indicated by the brackets in column 1 of table II, shows that the differences are highly significant (see foot of table II) The chief points of difference lie in the numbers with no detectable antitoxin, and to a lesser degree in those with over 0 1 unit per ml District N provided an abnormally large number of high values, 20% being 1 unit or higher 11 samples from M and 10 from D contained 1 unit or more, but only 2 samples of such value were obtained from district I Barr (1950) has already shown that the number of samples with no detectable antitoxin in any population may give no indication of the mean value or the scatter of the remainder Table II shows that the number of high values, over 0 5 or 1 unit, is unrelated to the values of the rest of the population It is clear that some difficulty would be encountered in formulating a simple scheme of immunisation for district N, owing to the large scatter of values and the number of high titres found in this population It should be noted that the only sample with a value of over 20 units was obtained from that district Table II shows that values of 10 units per ml or higher are rare, only 5 of the 1500 samples (0·33%) reached or exceeded this figure Slightly lower values would have been expected had the blood samples been taken from the mothers, because Barr et al. (1949) found that the antitoxic content of cord blood was usually appreciably higher and might be double that of the mother's blood taken during labour This observation has recently been confirmed by Murray et al. (1950), who compared the staphylococcal antitoxic titres of serum from cord blood, and mothers' and infants' blood.

The main peaking in value in the distributions shown in table II occurs over the range 0 04, 0 1, 0 2, 0 5 unit, but in several cases there is a suggestion of a lower peak, usually at 0 004 unit per ml , this is especially evident in districts D and M

TABLE III—DISTRIBUTION OF ANTITOXIC VALUES AMONG SERIES OF 100 CORD BLOOD SAMPLES FROM FIVE INDUSTRIAL TOWNS

$\chi^2 = 15\ 685 \quad 16$ D F $\quad P = 0\ 48$

COMPARISON OF VALUES FROM VARIOUS AREAS

As we have already stated, Barr et al (1949) found that the distributions of values in samples from two districts of South East London were not significantly different A third district of London has now been investigated, 100 samples from Queen Charlotte's Hospital being examined, and a comparison has been made between these three series of samples The differences found were not significant ($\chi^2 = 8\ 005$ 4 D F $P = 0\ 093$), the value of P was considerably lower however than that obtained by Barr et al for the South East London samples The chief difference between the districts lay in the smaller number of low values (under 0 01) in the South East London series

A comparison has been made between five industrial towns in the provinces—Birmingham, Coventry, Leeds, Rochdale, and West Bromwich—and the results are

own in table III. These districts are represented as D, E, H, and M in table II, but the sequence is not stated above. There is no significant difference tween the distributions of values of blood samples om these areas, and the differences between districts and M are not significant when compared alone, except r the numbers with and without detectable antitoxin.

Comparisons have also been made between samples om the London area and from these same five provincial wns, and table IV shows that the differences in distriution are highly significant. The analysis shows that ie number of samples with less than 0·01 unit per ml. below expectation in the London series, the number etween 0·01 and 0·2 exceeds expectation, while the umber of high-value samples, above 0·5 unit, is approxiiately equal to the expected number. The differences etween the distributions are even greater if the West ondon samples (Queen Charlotte's Hospital) are excluded or the latter are statistically comparable with the rovincial samples ($\chi^2 = 4{\cdot}019$ 4 D.F. P = 0·41).

It is unfortunately impossible to make any comparison etween strictly rural and urban districts, because many of the towns included in the survey receive patients from outlying rural areas.

ABLE IV—COMPARISON OF DISTRIBUTION OF ANTITOXIC VALUES AMONG CORD-BLOOD SAMPLES FROM LONDON AND FIVE INDUSTRIAL TOWNS IN THE PROVINCES

Antitoxic value (unit per ml.)	Percentage of samples from		Total no. of samples
	London	Industrial towns	
Under 0·001	25·0	35·8	263
0·001–0·004	5·0	9·4	62
0·01–0·04	22·0	15·6	144
0·1–0·2	29·0	21·6	195
0·5 and over	16·0	17·6	136
Total	300	500	800

$\chi^2 = 16{\cdot}914$ 4 D.F. P = <0·01

Possibly differences which may have existed in the past between the antitoxic values of people from rural and urban districts are now reduced to some extent because of the greater movements of the population in recent times. Of a small number of samples received from a rural area, however, and not included in table II few contained any detectable antitoxin.

EFFECT OF EPIDEMICS

Certain towns included in this survey have experienced severe epidemics within the last twenty years. The distribution of antitoxic values from these areas does not differ from those of similar towns which have not experienced such epidemics. This may possibly be explained by the long lapse of time between the epidemics and the sampling of the population. It is possible that many of the mothers were not then residing in the area affected by the epidemic. The percentage of mothers in each of two such towns, who stated that they had had diphtheria, was less than half those in 6 out of 8 other districts returning information. There is no reason to suppose that the information from these towns was less reliable than that from the other 8. There are insufficient figures from immunised mothers for any conclusions to be drawn as to the relative success of methods of immunisation in different districts. The wide age group covered would necessitate the examination of very large numbers of samples.

AGE AT WHICH IMMUNISATION COULD BE STARTED

It has already been shown (Barr 1950) that the numbers of babies born in Coventry and Southwark (S.E. London) with antitoxic values below the Schick level were significantly different; the numbers in these areas that could be satisfactorily immunised at the age of 3 months, however, were not significantly different.

Table V gives the approximate Schick-positive rates of the mothers in each of the fifteen districts of this survey. For this purpose all with cord-blood values under 0·004 unit per ml. have been recorded as Schick-positive, and those with values of 0·004 unit or higher as Schick-negative. The figures therefore give only a fair approximation to the result which would have been obtained had the Schick test actually been carried out; probably they provide a slightly lower estimate, in view of the higher titre of cord-blood. Very considerable differences, which are clearly highly significant, exist between the approximate Schick positive rates in the fifteen districts ($\chi^2 = 73{\cdot}718$ 14 D.F. P = <0·001). The figures range from 23 in district O to 62 in district A, with an average of 37·6. It will be seen that the order of the figures from A to O is roughly, but not exactly, the same as that in table II, where the number of samples with no detectable antitoxin is given.

Table V also shows the numbers of babies that could be satisfactorily immunised if they received their first dose of A.P.T. at birth and at the age of 3, 6, and 8 months; these figures were obtained by calculation and represent the numbers whose level of maternally conferred antitoxin would have fallen below 0·04 unit per ml. at these ages. Very considerable differences exist between the numbers that could be immunised at birth, and the average number is just over 50% for the 1500 samples. At the age of 3 months the differences are greatly reduced, ranging from 70 in district O to 93 in district A; these differences are highly significant ($\chi^2 = 38{\cdot}097$ 14 D.F. P = <0·001). A study of the table shows that the greatest deviation from the mean is provided by district N, and, if this figure is omitted from the analysis, the value of P becomes 0·05. At the age of 6 months 96·3% of the babies could be successfully immunised (though only 89% in district N), and little is gained by further delaying the first dose of prophylactic until the age of 8 months, officially recommended at present.

It is abundantly clear from table V that, as noted before (Barr 1950), little useful information as to when immunisation can be started in a population is provided

Possibly differences which may have existed in the past between the antitoxic values of people from rural and urban districts are now reduced to some extent because of the greater movements of the population in recent times Of a small number of samples received from a rural area, however, and not included in table II few contained any detectable antitoxin

EFFECT OF EPIDEMICS

Certain towns included in this survey have experienced severe epidemics within the last twenty years The distribution of antitoxic values from these areas does not differ from those of similar towns which have not experienced such epidemics This may possibly be explained by the long lapse of time between the epidemics and the sampling of the population It is possible that many of the mothers were not then residing in the area affected by the epidemic The percentage of mothers in each of two such towns, who stated that they had had diphtheria, was less than half those in 6 out of 8 other districts returning information There is no reason to suppose that the information from these towns was less reliable than that from the other 8 There are insufficient figures from immunised mothers for any conclusions to be drawn as to the relative success of methods of immunisation in different districts The wide age group covered would necessitate the examination of very large numbers of samples

AGE AT WHICH IMMUNISATION COULD BE STARTED

It has already been shown (Barr 1950) that the numbers of babies born in Coventry and Southwark (S.E London) with antitoxic values below the Schick level were significantly different, the numbers in these areas that could be satisfactorily immunised at the age of 3 months however, were not significantly different

Table V gives the approximate Schick-positive rates of the mothers in each of the fifteen districts of this survey For this purpose all with cord-blood values under 0 004 unit per ml. have been recorded as Schick-positive, and those with values of 0 004 unit or higher as Schick negative The figures therefore give only a fair approximation to the result which would have been obtained had the Schick test actually been carried out probably they provide a slightly lower estimate in view of the higher titre of cord blood Very considerable differences, which are clearly highly significant, exist between the approximate Schick-positive rates in the fifteen districts (χ^2 = 73 718 14 D.F P = <0·001) The figures range from 23 in district O to 62 in district A, with an average of 37 6 It will be seen that the order of the figures from A to O is roughly, but not exactly, the same as that in table II, where the number of samples with no detectable antitoxin is given

Table V also shows the numbers of babies that could be satisfactorily immunised if they received their first dose of A.P.T at birth and at the age of 3, 6, and 8 months, these figures were obtained by calculation and represent the numbers whose level of maternally conferred antitoxin would have fallen below 0 04 unit per ml. at these ages Very considerable differences exist between the numbers that could be immunised at birth, and the average number is just over 50% for the 1500 samples At the age of 3 months the differences are greatly reduced, ranging from 70 in district O to 93 in district A, these differences are highly significant (χ^2 = 38 097 14 D.F P = <0 001) A study of the table shows that the greatest deviation from the mean is provided by district N, and, if this figure is omitted from the analysis, the value of P becomes 0·05 At the age of 6 months 96 3% of the babies could be successfully immunised (though only 89% in district N), and little is gained by further delaying the first dose of prophylactic until the age of 8 months, officially recommended at present

It is abundantly clear from table V that, as noted before (Barr 1950) little useful information as to when immunisation can be started in a population is provided

TABLE I—COMPARISON OF DISTRIBUTION OF ANTITOXIC VALUES IN TWO CONSECUTIVE SERIES EACH OF 100 CORD BLOOD SAMPLES FROM THE SAME TOWN

Antitoxic values (units per ml)	No of cord blood samples		
	Series 1	Series 2	Total
Under 0 001	41	32	73
0 001 0 002 0 004	9	11	20
0 01 0 02 0 04	17	19	36
0 1 0 2, 0 5	23	30	53
1 0 2 0, 5 0	10	8	18
Total	100	100	200

χ^2 = 2 568 4 D F P = 0 635

will be seen that there was no significant difference in distribution between the two series, and a high value of P (0 635) was obtained It was therefore concluded that a sample of 100 is adequate for statistical comparisons

DISTRIBUTION OF VALUES

Table II shows in detail the distribution of values from all fifteen districts investigated These have been arranged in order according to the numbers with no detectable antitoxin, and the districts have been named from A to O to preserve anonymity The numbers with less than 0 001 unit per ml range from 59 in district A to 21 in district O, with an average of 34 8 The differences between the numbers with and without detectable antitoxin are highly significant (χ^2 = 64 29 14 D F P = < 0 001) A comparison of the general distribution of values, arranged in groups as indicated by the brackets in column 1 of table II, shows that the differences are highly significant (see foot of table II) The chief points of difference lie in the numbers with no detectable antitoxin, and to a lesser degree in those with over 0 1 unit per ml District N provided an abnormally large number of high values, 20% being 1 unit or higher 11 samples from M and 10 from D contained 1 unit or more, but only 2 samples of such value were obtained from district I Barr (1950) has already shown that the number of samples with no detectable antitoxin in any population may give no indication of the mean value or the scatter of the remainder Table II shows that the number of high values, over 0 5 or 1 unit, is unrelated to the values of the rest of the population It is clear that some difficulty would be encountered in formulating a simple scheme of immunisation for district N, owing to the large scatter of values and the number of high titres found in this population It should be noted that the only sample with a value of over 20 units was obtained from that district Table II shows that values of 10 units per ml or higher are rare, only 5 of the 1500 samples (0 33%) reached or exceeded this figure Slightly lower values would have been expected had the blood samples been taken from the mothers, because Barr et al. (1949) found that the antitoxic content of cord blood was usually appreciably higher and might be double that of the mother's blood taken during labour This observation has recently been confirmed by Murray et al. (1950), who compared the staphylococcal antitoxic titres of serum from cord blood, and mothers' and infants' blood.

The main peaking in value in the distributions shown in table II occurs over the range 0 04, 0 1, 0 2, 0 5 unit, but in several cases there is a suggestion of a lower peak, usually at 0 004 unit per ml, this is especially evident in districts D and M

TABLE III—DISTRIBUTION OF ANTITOXIC VALUES AMONG SERIES OF 100 CORD BLOOD SAMPLES FROM FIVE INDUSTRIAL TOWNS

χ^2 = 15 685 10 D F P = 0 48

COMPARISON OF VALUES FROM VARIOUS AREAS

As we have already stated, Barr et al (1949) found that the distributions of values in samples from two districts of South-East London were not significantly different A third district of London has now been investigated, 100 samples from Queen Charlotte's Hospital being examined, and a comparison has been made between these three series of samples The differences found were not significant (χ^2 = 8 005 4 D F P = 0 093), the value of P was considerably lower however than that obtained by Barr et al. for the South-East London samples The chief difference between the districts lay in the smaller number of low values (under 0 01) in the South East London series

A comparison has been made between five industrial towns in the provinces—Birmingham, Coventry, Leeds, Rochdale, and West Bromwich—and the results are

26	96	98	98	95	96	98	98	98	99	98	96	93	96	89	97	1445 (96 3%)
34	100	99	99	99	99	100	99	100	100	100	100	97	99	95	100	1486 (99 1%)

shown in table III These districts are represented as C, D, E, H, and M in table II, but the sequence is not as stated above There is no significant difference between the distributions of values of blood samples from these areas, and the differences between districts C and M are not significant when compared alone, except for the numbers with and without detectable antitoxin

Comparisons have also been made between samples from the London area and from these same five provincial towns, and table IV shows that the differences in distribution are highly significant The analysis shows that the number of samples with less than 0·01 unit per ml is below expectation in the London series, the number between 0 01 and 0 2 exceeds expectation, while the number of high value samples, above 0 5 unit, is approximately equal to the expected number The differences between the distributions are even greater if the West London samples (Queen Charlotte's Hospital) are excluded for the latter are statistically comparable with the provincial samples (χ^2 = 4 019 4 D F P = 0 41)

It is unfortunately impossible to make any comparison between strictly rural and urban districts, because many of the towns included in the survey receive patients from outlying rural areas

TABLE IV—COMPARISON OF DISTRIBUTION OF ANTITOXIC VALUES AMONG CORD BLOOD SAMPLES FROM LONDON AND FIVE INDUSTRIAL TOWNS IN THE PROVINCES

Antitoxic value (unit per ml)	Percentage of samples from		Total no of samples
	London	Industrial towns	
Under 0 001	28 0	35 8	263
0 001–0 004	5 0	9·4	62
0·01–0 04	22 0	15 6	144
0 1 0 2	29 0	21 6	195
0 5 and over	16 0	17 6	136
Total	300	500	800

χ^2 = 16 914 4 D F P = <0 01

Possibly differences which may have existed in the past between the antitoxic values of people from rural and urban districts are now reduced to some extent because of the greater movements of the population in recent times Of a small number of samples received from a rural area, however, and not included in table II few contained any detectable antitoxin

EFFECT OF EPIDEMICS

Certain towns included in this survey have experienced severe epidemics within the last twenty years The distribution of antitoxic values from these areas does not differ from those of similar towns which have not experienced such epidemics This may possibly be explained by the long lapse of time between the epidemics and the sampling of the population It is possible that many of the mothers were not then residing in the area affected by the epidemic The percentage of mothers in each of two such towns, who stated that they had had diphtheria, was less than half those in 6 out of 8 other districts returning information There is no reason to suppose that the information from these towns was less reliable than that from the other 8 There are insufficient figures from immunised mothers for any conclusions to be drawn as to the relative success of methods of immunisation in different districts The wide age group covered would necessitate the examination of very large numbers of samples

AGE AT WHICH IMMUNISATION COULD BE STARTED

It has already been shown (Barr 1950) that the numbers of babies born in Coventry and Southwark (S E London) with antitoxic values below the Schick level were significantly different, the numbers in these areas that could be satisfactorily immunised at the age of 3 months, however, were not significantly different

Table V gives the approximate Schick positive rates of the mothers in each of the fifteen districts of this survey For this purpose all with cord-blood values under 0 004 unit per ml have been recorded as Schick-positive, and those with values of 0 004 unit or higher as Schick negative The figures therefore give only a fair approximation to the result which would have been obtained had the Schick test actually been carried out probably they provide a slightly lower estimate, in view of the higher titre of cord blood Very considerable differences, which are clearly highly significant, exist between the approximate Schick positive rates in the fifteen districts (χ^2 = 73 718 14 D F P = <0 001) The figures range from 23 in district 0 to 62 in district A, with an average of 37 6 It will be seen that the order of the figures from A to O is roughly, but not exactly, the same as that in table II, where the number of samples with no detectable antitoxin is given

Table V also shows the numbers of babies that could be satisfactorily immunised if they received their first dose of A.P T at birth and at the age of 3, 6, and 8 months, these figures were obtained by calculation and represent the numbers whose level of maternally conferred antitoxin would have fallen below 0 04 unit per ml at these ages Very considerable differences exist between the numbers that could be immunised at birth, and the average number is just over 50% for the 1500 samples At the age of 3 months the differences are greatly reduced, ranging from 70 in district 0 to 93 in district A, these differences are highly significant (χ^2 = 38 097 14 D.F P = <0 001) A study of the table shows that the greatest deviation from the mean is provided by district N, and, if this figure is omitted from the analysis, the value of P becomes 0 05 At the age of 6 months 96 3% of the babies could be successfully immunised (though only 89% in district N), and little is gained by further delaying the first dose of prophylactic until the age of 8 months, officially recommended at present

It is abundantly clear from table V that, as noted before (Barr 1950), little useful information as to when immunisation can be started in a population is provided

TABLE I—COMPARISON OF DISTRIBUTION OF ANTITOXIC VALUES IN TWO CONSECUTIVE SERIES EACH OF 100 CORD BLOOD SAMPLES FROM THE SAME TOWN

Antitoxic values (units per ml.)	No. of cord blood samples		
	Series 1	Series 2	Total
Under 0.001	41	32	73
0.001, 0.002, 0.004	9	11	20
0.01, 0.02, 0.04	17	19	36
0.1, 0.2, 0.5	23	30	53
1.0, 2.0, 5.0	10	8	18
Total	100	100	200

$\chi^2 = 2.563$ 4 D.F. P = 0.635

will be seen that there was no significant difference in distribution between the two series, and a high value of P (0.635) was obtained. It was therefore concluded that a sample of 100 is adequate for statistical comparisons.

DISTRIBUTION OF VALUES

Table II shows in detail the distribution of values from all fifteen districts investigated. These have been arranged in order according to the numbers with no detectable antitoxin, and the districts have been named from A to O to preserve anonymity. The numbers with less than 0.001 unit per ml. range from 59 in district A to 21 in district O, with an average of 34.8. The differences between the numbers with and without detectable antitoxin are highly significant ($\chi^2 = 64.29$ 14 D.F. P = < 0.001). A comparison of the general distribution of values, arranged in groups as indicated by the brackets in column 1 of table II, shows that the differences are highly significant (see foot of table II). The chief points of difference lie in the numbers with no detectable antitoxin, and to a lesser degree in those with over 0.1 unit per ml. District N provided an abnormally large number of high values, 20% being 1 unit or higher. 11 samples from M and 10 from D contained 1 unit or more, but only 2 samples of such value were obtained from district I. Barr (1950) has already shown that the number of samples with no detectable antitoxin in any population may give no indication of the mean value or the scatter of the remainder. Table II shows that the number of high values, over 0.5 or 1 unit, is unrelated to the values of the rest of the population. It is clear that some difficulty would be encountered in formulating a simple scheme of immunisation for district N, owing to the large scatter of values and the number of high titres found in this population. It should be noted that the only sample with a value of over 20 units was obtained from that district. Table II shows that values of 10 units per ml. or higher are rare, only 5 of the 1500 samples (0.33%) reached or exceeded this figure. Slightly lower values would have been expected had the blood samples been taken from the mothers, because Barr et al. (1949) found that the antitoxic content of cord blood was usually appreciably higher and might be double that of the mother's blood taken during labour. This observation has recently been confirmed by Murray et al. (1950), who compared the staphylococcal antitoxic titres of serum from cord blood, and mothers' and infants' blood.

The main peaking in value in the distributions shown in table II occurs over the range 0.04, 0.1, 0.2, 0.5 unit, but in several cases there is a suggestion of a lower peak, usually at 0.004 unit per ml.; this is especially evident in districts D and M.

TABLE III—DISTRIBUTION OF ANTITOXIC VALUES AMONG SERIES OF 100 CORD BLOOD SAMPLES FROM FIVE INDUSTRIAL TOWNS

$\chi^2 = 15.685$ 16 D.F. P = 0.48

COMPARISON OF VALUES FROM VARIOUS AREAS

As we have already stated, Barr et al. (1949) found that the distributions of values in samples from two districts of South East London were not significantly different. A third district of London has now been investigated, 100 samples from Queen Charlotte's Hospital being examined, and a comparison has been made between these three series of samples. The differences found were not significant ($\chi^2 = 8.005$ 4 D.F. P = 0.093), the value of P was considerably lower however than that obtained by Barr et al. for the South-East London samples. The chief difference between the districts lay in the smaller number of low values (under 0.01) in the South East London series.

A comparison has been made between five industrial towns in the provinces—Birmingham, Coventry, Leeds, Rochdale, and West Bromwich—and the results are

shown in table III These districts are represented as C, D, E, H, and M in table II, but the sequence is not as stated above There is no significant difference between the distributions of values of blood samples from these areas, and the differences between districts C and M are not significant when compared alone, except for the numbers with and without detectable antitoxin

Comparisons have also been made between samples from the London area and from these same five provincial towns, and table IV shows that the differences in distribution are highly significant The analysis shows that the number of samples with less than 0·01 unit per ml is below expectation in the London series, the number between 0 01 and 0 2 exceeds expectation, while the number of high value samples, above 0 5 unit, is approximately equal to the expected number The differences between the distributions are even greater if the West London samples (Queen Charlotte's Hospital) are excluded for the latter are statistically comparable with the provincial samples ($\chi^2 = 4\ 019$ 4 D F P = 0 41)

It is unfortunately impossible to make any comparison between strictly rural and urban districts, because many of the towns included in the survey receive patients from outlying rural areas.

TABLE IV—COMPARISON OF DISTRIBUTION OF ANTITOXIC VALUES AMONG CORD BLOOD SAMPLES FROM LONDON AND FIVE INDUSTRIAL TOWNS IN THE PROVINCES

Antitoxic value (unit per ml)	Percentage of samples from		Total no of samples
	London	Industrial towns	
Under 0 001	28 0	35 8	263
0 001–0 004	5 0	9·4	62
0 01–0 04	22 0	15 6	144
0 1 0 2	29 0	21 6	195
0 5 and over	16 0	17 6	136
Total	300	500	800

χ^2 = 16 914 4 D F P = <0 01

Possibly differences which may have existed in the past between the antitoxic values of people from rural and urban districts are now reduced to some extent because of the greater movements of the population in recent times Of a small number of samples received from a rural area, however, and not included in table II few contained any detectable antitoxin

EFFECT OF EPIDEMICS

Certain towns included in this survey have experienced severe epidemics within the last twenty years The distribution of antitoxic values from these areas does not differ from those of similar towns which have not experienced such epidemics This may possibly be explained by the long lapse of time between the epidemics and the sampling of the population It is possible that many of the mothers were not then residing in the area affected by the epidemic The percentage of mothers in each of two such towns, who stated that they had had diphtheria, was less than half those in 6 out of 8 other districts returning information There is no reason to suppose that the information from these towns was less reliable than that from the other 8 There are insufficient figures from immunised mothers for any conclusions to be drawn as to the relative success of methods of immunisation in different districts The wide age group covered would necessitate the examination of very large numbers of samples

AGE AT WHICH IMMUNISATION COULD BE STARTED

It has already been shown (Barr 1950) that the numbers of babies born in Coventry and Southwark (S E London) with antitoxic values below the Schick level were *significantly different*, the numbers in these areas that could be satisfactorily immunised at the age of 3 months, however, were not significantly different

Table V gives the approximate Schick positive rates of the mothers in each of the fifteen districts of this survey For this purpose all with cord-blood values under 0 004 unit per ml have been recorded as Schick-positive, and those with values of 0 004 unit or higher as Schick negative The figures therefore give only a fair approximation to the result which would have been obtained had the Schick test actually been carried out probably they provide a slightly lower estimate, in view of the higher titre of cord blood Very considerable differences, which are clearly highly significant, exist between the approximate Schick positive rates in the fifteen districts (χ^2 = 73 718 14 D.F P = <0 001) The figures range from 23 in district O to 62 in district A, with an average of 37 6 It will be seen that the order of the figures from A to O is roughly, but not exactly, the same as that in table II, where the number of samples with no detectable antitoxin is given

Table V also shows the numbers of babies that could be satisfactorily immunised if they received their first dose of A.P T at birth and at the age of 3, 6, and 8 months, these figures were obtained by calculation and represent the numbers whose level of maternally conferred antitoxin would have fallen below 0 04 unit per ml at these ages Very considerable differences exist between the numbers that could be immunised at birth, and the average number is just over 50% for the 1500 samples At the age of 3 months the differences are greatly reduced, ranging from 70 in district O to 93 in district A, these differences are highly significant (χ^2 = 38 097 14 D.F P = <0 001) A study of the table shows that the greatest deviation from the mean is provided by district N, and, if this figure is omitted from the analysis, the value of P becomes 0 05 At the age of 6 months 96 3% of the babies could be successfully immunised (though only 89% in district N), and little is gained by further delaying the first dose of prophylactic until the age of 8 months, officially recommended at present

It is abundantly clear from table V that, as noted before (Barr 1950), little useful information as to when immunisation can be started in a population is provided

TABLE I—COMPARISON OF DISTRIBUTION OF ANTITOXIC VALUES IN TWO CONSECUTIVE SERIES EACH OF 100 CORD BLOOD SAMPLES FROM THE SAME TOWN

Antitoxic values (units per ml)	No of cord blood samples		
	Series 1	Series 2	Total
Under 0 001	41	32	73
0 001 0 002 0 004	9	11	20
0 01 0 02 0 04	17	19	36
0 1 0 2 0 5	23	30	53
1 0, 2 0, 5 0	10	8	18
Total	100	100	200

χ^2 = 2 508 4 D F P = 0 635

will be seen that there was no significant difference in distribution between the two series, and a high value of P (0 635) was obtained It was therefore concluded that a sample of 100 is adequate for statistical comparisons

DISTRIBUTION OF VALUES

Table II shows in detail the distribution of values from all fifteen districts investigated These have been arranged in order according to the numbers with no detectable antitoxin, and the districts have been named from A to O to preserve anonymity The numbers with less than 0 001 unit per ml range from 59 in district A to 21 in district O, with an average of 34 8 The differences between the numbers with and without detectable antitoxin are highly significant ($\chi^2 = 64\ 29$ 14 D F P = < 0 001) A comparison of the general distribution of values, arranged in groups as indicated by the brackets in column 1 of table II, shows that the differences are highly significant (see foot of table II) The chief points of difference lie in the numbers with no detectable antitoxin, and to a lesser degree in those with over 0 1 unit per ml District N provided an abnormally large number of high values, 20% being 1 unit or higher 11 samples from M and 10 from D contained 1 unit or more, but only 2 samples of such value were obtained from district I Barr (1950) has already shown that the number of samples with no detectable antitoxin in any population may give no indication of the mean value or the scatter of the remainder Table II shows that the number of high values, over 0 5 or 1 unit, is unrelated to the values of the rest of the population It is clear that some difficulty would be encountered in formulating a simple scheme of immunisation for district N, owing to the large scatter of values and the number of high titres found in this population It should be noted that the only sample with a value of over 20 units was obtained from that district Table II shows that values of 10 units per ml or higher are rare, only 5 of the 1500 samples (0·33%) reached or exceeded this figure Slightly lower values would have been expected had the blood samples been taken from the mothers, because Barr et al. (1949) found that the antitoxic content of cord blood was usually appreciably higher and might be double that of the mother's blood taken during labour This observation has recently been confirmed by Murray et al (1950), who compared the staphylococcal antitoxic titres of serum from cord blood, and mothers' and infants' blood.

The main peaking in value in the distributions shown in table II occurs over the range 0 04, 0 1, 0 2, 0 5 unit, but in several cases there is a suggestion of a lower peak, usually at 0 004 unit per ml , this is especially evident in districts D and M

TABLE III—DISTRIBUTION OF ANTITOXIC VALUES AMONG SERIES OF 100 CORD BLOOD SAMPLES FROM FIVE INDUSTRIAL TOWNS

χ^2 = 15 685 16 D F P = 0 48

COMPARISON OF VALUES FROM VARIOUS AREAS

As we have already stated, Barr et al (1949) found that the distributions of values in samples from two districts of South-East London were not significantly different A third district of London has now been investigated, 100 samples from Queen Charlotte's Hospital being examined, and a comparison has been made between these three series of samples. The differences found were not significant ($\chi^2 = 8\ 005$ 4 D.F P = 0 093), the value of P was considerably lower however than that obtained by Barr et al. for the South East London samples The chief difference between the districts lay in the smaller number of low values (under 0 01) in the South East London series

A comparison has been made between five industrial towns in the provinces—Birmingham, Coventry, Leeds, Rochdale, and West Bromwich—and the results are

34	100	99	99	99	99	100	99	100	100	100	100	97	99	95	100	1486 (*99 1%*)

shown in table III These districts are represented as C, D, E, H, and M in table II, but the sequence is not as stated above There is no significant difference between the distributions of values of blood samples from these areas, and the differences between districts C and M are not significant when compared alone, except for the numbers with and without detectable antitoxin

Comparisons have also been made between samples from the London area and from these same five provincial towns, and table IV shows that the differences in distribution are highly significant The analysis shows that the number of samples with less than 0 01 unit per ml is below expectation in the London series, the number between 0 01 and 0 2 exceeds expectation, while the number of high value samples, above 0 5 unit, is approximately equal to the expected number The differences between the distributions are even greater if the West London samples (Queen Charlotte's Hospital) are excluded for the latter are statistically comparable with the provincial samples (χ^2 = 4 019 4 D F P = 0 41)

It is unfortunately impossible to make any comparison between strictly rural and urban districts, because many of the towns included in the survey receive patients from outlying rural areas

TABLE IV—COMPARISON OF DISTRIBUTION OF ANTITOXIC VALUES AMONG CORD BLOOD SAMPLES FROM LONDON AND FIVE INDUSTRIAL TOWNS IN THE PROVINCES

Antitoxic value (unit per ml)	Percentage of samples from		Total no of samples
	London	Industrial towns	
Under 0 001	28 0	35 8	263
0 001–0 004	5 0	9 4	62
0 01–0 04	22 0	15 6	144
0 1 0 2	20 0	21 6	195
0 5 and over	16 0	17 6	136
Total	300	500	800

χ^2 = 16 914 4 D F P = <0 01

Possibly differences which may have existed in the past between the antitoxic values of people from rural and urban districts are now reduced to some extent because of the greater movements of the population in recent times Of a small number of samples received from a rural area, however, and not included in table II few contained any detectable antitoxin

EFFECT OF EPIDEMICS

Certain towns included in this survey have experienced severe epidemics within the last twenty years The distribution of antitoxic values from these areas does not differ from those of similar towns which have not experienced such epidemics This may possibly be explained by the long lapse of time between the epidemics and the sampling of the population It is possible that many of the mothers were not then residing in the area affected by the epidemic The percentage of mothers in each of two such towns, who stated that they had had diphtheria, was less than half those in 6 out of 8 other districts returning information There is no reason to suppose that the information from these towns was less reliable than that from the other 8 There are insufficient figures from immunised mothers for any conclusions to be drawn as to the relative success of methods of immunisation in different districts The wide age group covered would necessitate the examination of very large numbers of samples

AGE AT WHICH IMMUNISATION COULD BE STARTED

It has already been shown (Barr 1950) that the numbers of babies born in Coventry and Southwark (S E London) with antitoxic values below the Schick level were significantly different, the numbers in these areas that could be satisfactorily immunised at the age of 3 months, however, were not significantly different

Table V gives the approximate Schick positive rates of the mothers in each of the fifteen districts of this survey For this purpose all with cord blood values under 0 004 unit per ml have been recorded as Schick-positive, and those with values of 0 004 unit or higher as Schick negative The figures therefore give only a fair approximation to the result which would have been obtained had the Schick test actually been carried out probably they provide a slightly lower estimate, in view of the higher titre of cord blood Very considerable differences, which are clearly highly significant, exist between the approximate Schick positive rates in the fifteen districts (χ^2 = 73 718 14 D.F P = <0 001) The figures range from 23 in district O to 62 in district A, with an average of 37 6 It will be seen that the order of the figures from A to O is roughly, but not exactly, the same as that in table II, where the number of samples with no detectable antitoxin is given

Table V also shows the numbers of babies that could be satisfactorily immunised if they received their first dose of A.P.T at birth and at the age of 3, 6, and 8 months, these figures were obtained by calculation and represent the numbers whose level of maternally conferred antitoxin would have fallen below 0 04 unit per ml at these ages Very considerable differences exist between the numbers that could be immunised at birth, and the average number is just over 50% for the 1500 samples At the age of 3 months the differences are greatly reduced, ranging from 70 in district O to 93 in district A, these differences are highly significant (χ^2 = 38 097 14 D F P = <0 001) A study of the table shows that the greatest deviation from the mean is provided by district N, and, if this figure is omitted from the analysis, the value of P becomes 0 05 At the age of 6 months 96 3% of the babies could be successfully immunised (though only 89% in district N), and little is gained by further delaying the first dose of prophylactic until the age of 8 months, officially recommended at present

It is abundantly clear from table V that, as noted before (Barr 1950), little useful information as to when immunisation can be started in a population is provided

TABLE I—COMPARISON OF DISTRIBUTION OF ANTITOXIC VALUES IN TWO CONSECUTIVE SERIES EACH OF 100 CORD BLOOD SAMPLES FROM THE SAME TOWN

Antitoxic values (units per ml)	No of cord blood samples		
	Series 1	Series 2	Total
Under 0 001	41	32	73
0 001 0 002 0 004	9	11	20
0 01 0 02 0 04	17	19	36
0 1, 0 2, 0 5	23	30	53
1 0 2 0 5 0	10	8	18
Total	100	100	200

χ^2 = 2 568 4 D F P = 0 635

will be seen that there was no significant difference in distribution between the two series, and a high value of P (0 635) was obtained It was therefore concluded that a sample of 100 is adequate for statistical comparisons

DISTRIBUTION OF VALUES

Table II shows in detail the distribution of values from all fifteen districts investigated These have been arranged in order according to the numbers with no detectable antitoxin, and the districts have been named from A to O to preserve anonymity The numbers with less than 0 001 unit per ml range from 59 in district A to 21 in district O, with an average of 34 8 The differences between the numbers with and without detectable antitoxin are highly significant (χ^2 = 64 29 14 D F P = < 0 001) A comparison of the general distribution of values, arranged in groups as indicated by the brackets in column 1 of table II, shows that the differences are highly significant (see foot of table II) The chief points of difference lie in the numbers with no detectable antitoxin, and to a lesser degree in those with over 0 1 unit per ml District N provided an abnormally large number of high values, 20% being 1 unit or higher 11 samples from M and 10 from D contained 1 unit or more, but only 2 samples of such value were obtained from district I Barr (1950) has already shown that the number of samples with no detectable antitoxin in any population may give no indication of the mean value or the scatter of the remainder Table II shows that the number of high values, over 0 5 or 1 unit, is unrelated to the values of the rest of the population It is clear that some difficulty would be encountered in formulating a simple scheme of immunisation for district N, owing to the large scatter of values and the number of high titres found in this population It should be noted that the only sample with a value of over 20 units was obtained from that district Table II shows that values of 10 units per ml or higher are rare, only 5 of the 1500 samples (0·33%) reached or exceeded this figure Slightly lower values would have been expected had the blood samples been taken from the mothers, because Barr et al (1949) found that the antitoxic content of cord blood was usually appreciably higher and might be double that of the mother's blood taken during labour This observation has recently been confirmed by Murray et al (1950), who compared the staphylococcal antitoxic titres of serum from cord-blood, and mothers' and infants' blood.

The main peaking in value in the distributions shown in table II occurs over the range 0 04, 0 1, 0 2, 0 5 unit, but in several cases there is a suggestion of a lower peak, usually at 0 004 unit per ml , this is especially evident in districts D and M

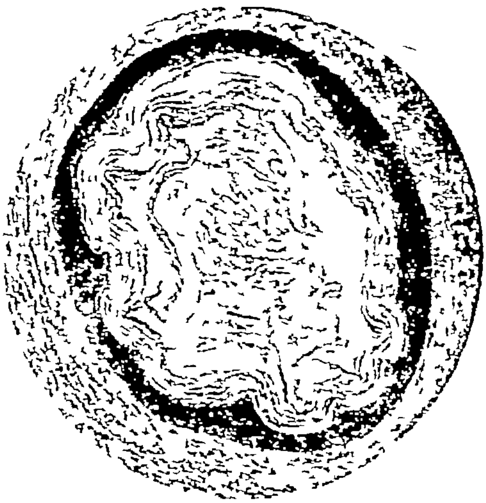

Fig 2—Cyst lined by squamous epithelium and containing concentric layers of keratin

ÆTIOLOGY

It appears therefore that the condition is one in which surface epithelium is displaced into the corium either in the form of single cells or cell nests, or by the invagination of the whole skin The result is the production of non specific inflammatory tissue and of implantation epidermoid cysts

The underlying cause is the piston action of the artificial leg Each time weight is put on the limb the stump is pushed into it and sustains pressure from the upper rim, mainly on its anterior and medial edge When the weight is taken off the leg, the pressure is released This oft repeated pressure and release presumably causes some displacement of the skin, and epithelium may be pushed inwards into the corium

Much has been written on epidermoid cysts following trauma either single (Le Fort 1894, Hartley 1896, King 1933 Yachnin and Summerill 1941, Ewing 1942, Pohlmann and Wachstein 1944, Stabb 1891), or repeated (King 1933) The cysts associated with artificial limbs have hitherto been regarded as sebaceous adenomata, but they should be recognised as post traumatic epidermoid cysts

CASE NOTES

Case 1 —Mrs A aged 34 Bilateral amputations above the knees after a railway accident in 1946 Started to wear artificial limbs in 1947 Three or four months later developed small painful lumps in the adductor regions, which improved with rest The lumps tended to become more painful and more evident in hot weather The local discomfort increased when the patient lost weight by dieting and the limbs fitted more loosely When examined in 1949 she had shotty thickening of the skin in the adductor regions of the thighs in a transverse direction corresponding to the level of the rims of the artificial legs Sections show the histological pictures described above

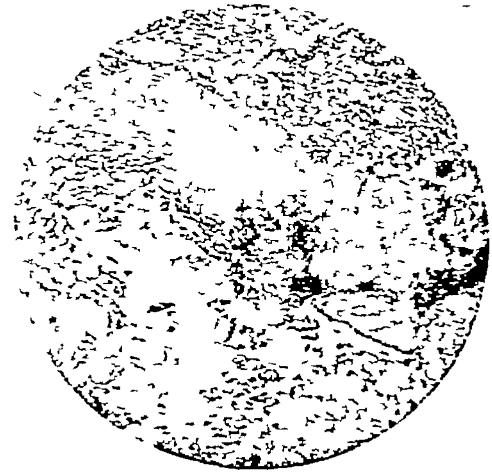

Fig 3—Fragment of skin epithelium lying free in the midst of chronic inflammatory cells.

Case 2 —Mrs B, aged 23 At 8 years the right leg was amputated above the knee following osteomyelitis She had an artificial limb soon afterwards, and eleven years later developed one small lump in the adductor region, "which remained uninfected for one year" This ultimately became infected and developed a discharging sinus Since then has had numerous lumps and the whole area is so painful that she cannot wear a prosthesis Examination showed thickening of the skin in the adductor region of the right leg in which small shotty nodules could be palpated (fig 1) Between the nodules the tissue appeared normal There was a well healed oblique scar, the site of previous operative removal of tissue Sections showed the typical histological picture

Case 3 —Mr C aged 47 Amputation of left leg above the knee twenty years ago Developed small lumps in the adductor region of the left leg fourteen months after starting to wear an artificial limb Lumps painful, and seemed to grow more in warm weather Had to discontinue wearing the limb for periods of two or three weeks at intervals of three or four months to allow the lumps to "settle" The area affected gradually became larger and at the time of examination the patient had been unable to wear the leg for eighteen months Thickening and lumpiness were evident in the adductor region of the thigh in a line corresponding with the upper edge of the artificial limb There were several painful lumps with reddened skin over them and discharging sinuses, from which pus could be expressed The pus was sterile on culture and the cellular components were polymorphs and scanty epithelial cells Histological appearances were as described.

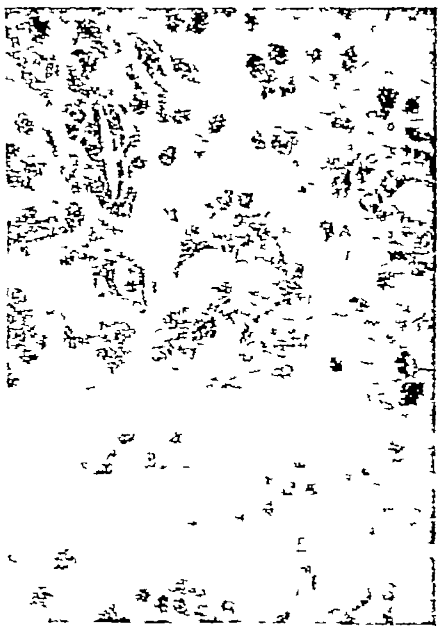

Fig 4—Chronic granulation tissue showing large giant-cell enclosing cornified epithelial cell

Case 4 —Mr D, aged 50 Amputation of right leg above the knee in first world war Developed lumps in the right adductor region which later became painful and formed discharging sinuses Unable to wear limb for six months Histological appearances characteristic.

Case 5 —Mr E, aged 29 Amputation above the left knee following compound fracture Developed lumps in the adductor region, which were painful and worse in hot weather They subsided with rest At the time of examination the patient was unable to wear his artificial leg Histological appearances characteristic

SUMMARY

Cases are described in which patients wearing the type of artificial leg usual in this country have developed a skin lesion in the adductor region of the thigh

by the results of Schick testing For instance, in district B about 56% of babies were born with antitoxic values below the Schick level compared with 32% in district I, at the age of 3 months 90% of babies in B and 91% in I could receive their first dose of prophylactic In referring to successful immunisation the criteria of Barr et al (1950) have been adopted They obtained, in babies about 2 months after the second dose of A P T, normally distributed antitoxic values with a mean of about 0 2 unit per ml

SUMMARY

Titrations for diphtheria antitoxin have been made on 100 samples of cord blood from each of fifteen districts of the British Isles Highly significant differences exist between the distributions of values of samples from the various areas

Statistically comparable distributions were obtained from five industrial towns in the provinces, but these were significantly different from those of the London area

Very considerable differences existed between the approximate Schick positive rates and the number of high values in the various areas These differences could not be explained by earlier epidemics or methods of immunisation, the interval elapsing since serious epidemics is probably too great to exert any influence at present

The Schick test would give little useful information as to when immunisation could be started in the babies with expectation of success

We are greatly indebted to the following collaborators for supplying the samples of cord blood and for much valuable information Prof D Baird, Dr H J Rae, and Dr J Smith in Aberdeen, Dr J Hallum and Dr J McGarrity in Birmingham, Dr Scott Thomson in Cardiff, Dr J Paterson in Castleford, Dr J C Saunders in Cork, Mr H R Duval and Dr J F Galpine in Coventry, Dr J Bruce Dewar in Dumfries, Dr T Anderson and Dr E Hutton Brown in Glasgow, Prof A M Claye in Leeds, Dr K J Randall in S E London, Dr J Murray in W London, Dr J Innes in Rochdale, Dr E S Thomas in Stratford on Avon, and Dr J Tudor Lewis in West Bromwich Without their interest and coöperation the investigation could not have been made

PATHOLOGIST, WILLESDEN GENERAL HOSPITAL, LATE
PATHOLOGIST, EAST HAM MEMORIAL HOSPITAL

There seems to be only one reference in the literature to epidermoid cysts in amputation stumps (Ministry of Pensions 1939) yet the condition is one which causes considerable inconvenience and financial loss to the patient, and much concern to those interested in his welfare

In a typical case the cysts first appear when the patient has worn an artificial limb for some months or years—usually after an above knee amputation Small lumps then develop in the skin of the adductor region of the thigh along the upper edge of the prosthesis In the early stages they disappear when the stump is rested, but in time they may become larger and more numerous the skin breaks down, "pus" is discharged, and the discharging sinus may become chronic The skin in the affected region often becomes pigmented (fig 1) At this stage it is impossible to wear the prosthesis, and the patient either becomes bedridden or takes to a crutch

No entirely satisfactory treatment has yet been devised, but attempts have been made to relieve the condition by excision of the affected area

PATHOLOGY

The specimens received from the surgeons consist of an elliptical pigmented piece of skin with underlying tissues On cutting through such a specimen at right angles to the skin surface one sees small round areas which appear to be abscesses, some with central softening There are also some round zones, outlined in the formol fixed tissue by a thin white line Microscopical examination shows zones of non specific inflammatory tissue composed of lymphocytes, plasma cells, and polymorphs, surrounded by young capillaries and fibroblasts or fibrous tissue Foreign body giant cells are always present and may be collected into follicles, some of which have a central cavity containing amorphous eosinophilic material There are also small cystic spaces lined with stratified squamous epithelium, these contain no hairs or sweat glands, and usually no dermal papillæ, and they are filled with concentric layers of keratin (fig 2) Some of the cysts are surrounded by, or are in close contact with, the inflammatory cells Most of them are microscopic in size, but some are large enough to be seen with the naked eye, and their lining of skin then appears as a thin white line

In some places there are fragments of readily recognisable skin epithelium in the chronic inflammatory tissue (fig 3) We were anxious to discover the contents of the slit like vacuoles in many of the foreign body giant cells and of the cystic spaces in which some of them lie However, neither polariscopic examination, nor staining with Scharlach R or Nile blue sulphate, or by the Golodetz, Windaus, or Schultz techniques (Mallory 1938) showed the presence of anisotropic material or of any fatty substance.

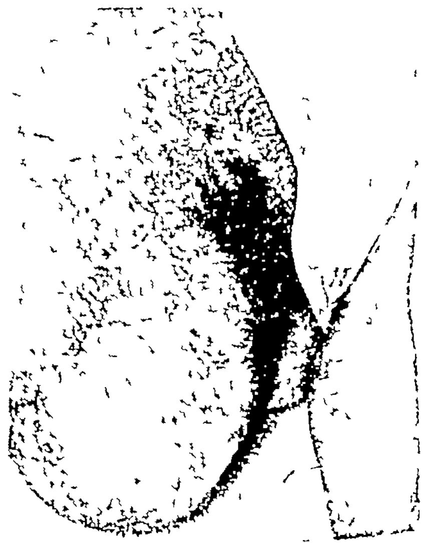

Fig 1—Amputation stump showing pigmented skin and sinuses and nodules along upper antero medial line of apposition of prosthesis.

Among the chronic inflammatory cells are scattered a few large rounded cells with small nuclei which closely resemble cornified epithelial cells Using Papanicolaou's water blue stain (Papanicolaou 1933) it was found that these cells stain as cornified epithelial cells, and with Mallory's aniline blue collagen stain (Mallory 1938) they take on the same crimson colour as cornified skin epithelium Examination with these stains shows that some of the giant cells contain fragments of similar material, and fig 4 shows a giant cell within which a complete epithelial cell can be identified No fragments of collagen (Pullinger 1942) could be demonstrated in these cells

The "pus" obtained from the discharging sinus contains not only polymorphs but also squamous epithelial cells No single infective organism has been identified

inoculated on to the chorioallantois of developing chick embryos, but only ill defined lesions developed after 3 days' incubation, and further egg passage was negative The remainder of the fluid was rubbed into linear scarifications on the loin of a sheep The animal developed a typical infection with the formation of vesicles along the line of scarification on the 4th day Smears made from the base of one vesicle on the 6th day after inoculation were stained by Gutstein's method These showed large numbers of minute particles of identical size and appearance, and many of them were associated with damaged host cells A typical field is shown in fig 2, and the particles are indistinguishable from those seen in stained smears made from the base of vesicles in cases of smallpox Smears of the same material stained by Gram did not reveal any bacteria

Histological examination of sections from the edge of one vesicle showed epithelial proliferation and reticular degeneration, but inclusion bodies were not found Material from these lesions was also inoculated into eggs, but the virus did not produce lesions after the first egg passage

Cross immunity Experiments

To confirm the identity of the human strain of virus, reciprocal cross immunity experiments were carried out in sheep with this strain and a known laboratory strain of C P D virus

Immunity Afforded by Human Strain —A sheep (3216) which had recovered from a widespread infection of the abdomen and thigh with the human virus was reinoculated on one thigh 18 days later with serial dilutions of 1/100 1/1000, 1/5000, 1/10,000, and 1/50 000 of the homologous virus, and on the other thigh with similar dilutions of the stock sheep strain (U F 1) A control sheep (3231) received the U.F 1 virus and the activity of the human strain was checked later in sheep 3240 There was no reaction in the protected sheep to either virus even with the 1/100 dilution The control animal (3231) showed typical lesions which were moderate at dilutions of 1/100 to 1/10,000 and slight at 1/50 000

Immunity Afforded by the Sheep Strain —Sheep 3231 which had recovered from infection with strain U.F 1 was reinoculated 29 days later with dilutions of the two viruses as outlined above The activity of the ovine strain had already been demonstrated the human strain was checked in control sheep 3240 Sheep 3231 was completely immune to both strains while sheep 3240 was fully susceptible

These cross immunity experiments demonstrate that the strain of virus recovered from the patient was immunologically indistinguishable from a standard strain of the virus of ovine contagious pustular dermatitis

DISCUSSION

The laboratory findings in this case confirmed a clinical diagnosis of infection with the virus of contagious pustular dermatitis One of us (G M L) has seen a considerable number of such infections in farm workers, and a clinical account of these will be published elsewhere The disease is well known among Australian sheep shearers, who have occasionally refused to handle infected flocks because of the likelihood of developing lesions on the hands and arms While a history of contact with infected sheep is a help in diagnosis, the possibility of infection with cowpox virus and certain bacterial infections must also be kept in mind Most laboratories have not the facilities to undertake the tests on sheep described here though these are at present the only certain means of diagnosis However, a full bacteriological examination would be useful, as would microscopic examination of smears made on glass slides from scrapings taken from the base of early lesions Culture of the material on the chorioallantois of the developing hen's egg should serve to distinguish between infection caused by cowpox and by C P D virus Cowpox virus produces typical lesions on the chorioallantois whereas C P D virus either fails to take or dies out rapidly on passage Serological methods of diagnosing human infection would be useful but we know little of their value Glover (1932) showed that the sera of hyperimmune sheep contained complement fixing antibodies and that weak reactions could be obtained from the sera of recovered natural cases in sheep Blakemore et al (1948) have also shown that agglutination takes place with patient's serum and washed elementary body suspensions Several cases of orf among butchers and other city workers have recently come to our notice, and various laboratory methods of diagnosis are now being investigated Until a simple test is available the clinical diagnosis of human infections with C P D virus will often go unconfirmed

SUMMARY

A case of natural transmission of the virus of ovine contagious pustular dermatitis to man is described The diagnosis was confirmed by infecting a sheep with the human material and by cross immunity tests

EXPERIMENTAL NYSTAGMUS

R C BROWNE
M A, D M Oxfd, M R C P
NUFFIELD PROFESSOR OF INDUSTRIAL HEALTH IN THE UNIVERSITY OF DURHAM

THE origin of coalminers' nystagmus has never been satisfactorily explained Some hold that it is primarily psychoneurotic (*Lancet* 1940, Halliday 1943) whereas others suggest that the chief cause is using the eye at levels of illumination below the threshold of perception by the cones, with the result that the fine normal scanning movements of the retina are grossly exaggerated because the macula is in effect blind and the eye has only peripheral vision at these low intensities of light (Ferguson 1943, Davson 1949)

One of the consequences of this conflict of opinion is that both doctors and pit managers tend to consider miners with nystagmus as "neurotic," while the victim and his workmates consider that he is "finished" The demonstration that darkness produces nystagmus in animals with visual apparatus analogous to that of man is therefore important

A cat's eye is similar to a man's in that the retina has both rods for seeing in "the dark" and cones for seeing at higher intensities of light, but there are proportionately fewer cones and relatively more rods to suit the cat's nocturnal habits The cat uses both eyes at once, and so strong is its urge towards binocular vision that, if the extrinsic eye muscles are detached from the eyeball and reattached in the wrong places, binocular vision is reinstituted in a few days (Walls 1942) In man half the fibres in the optic nerves do not cross in the chiasma, but in the cat about a third do not The nocturnal cat has a reflector, the tapetum, at the back of its rods and cones to increase their sensitivity, whereas in man, working at higher intensities of light by day, a pigmented "backing" in the choroid cuts down the scatter of the brighter light The visual systems of cat and man are therefore much alike both need and have binocular vision, the cat for accurate judgment of range and position when stalking and seizing its prey, and man for manipulation The differences between them are due to the different ranges of intensity of light under which the two species usually live

HUMAN INFECTION WITH THE VIRUS OF CONTAGIOUS PUSTULAR DERMATITIS

Contagious pustular dermatitis, or orf, is an infectious disease of sheep which is common in most sheep raising areas of this and other countries Affected animals develop a vesiculopapular eruption usually confined to the lips and surrounding tissue , but, in the severe form, lesions may also be present on the oral mucosa and on various other non wool bearing parts of the body The disease is prevalent in spring and summer and weaned lambs up to a year old are highly susceptible Aynaud (1923) showed that the disease is caused by a virus and this was confirmed by Glover (1928), who transmitted the infection with Berkefeld V filtrates of scrapings from infected animals to normal lambs Glover also showed by cross immunity tests that different sheep strains were immunologically identical

Veterinary surgeons and some physicians have long suspected that human infection was possible with the virus of contagious pustular dermatitis (C P D), but in most reported cases the evidence is circumstantial Thus Peterkin (1937) described five cases, but he did not demonstrate virus in the human lesions In the U S A , however Newsom and Cross (1934) transmitted infection from a human case to sheep but did not confirm its nature In Australia, Carne et al (1946) described three cases in which the nature of the lesions was investigated by infecting normal sheep from human material and by cross immunity tests There can be little doubt about the diagnosis in the patient described by Blakemore et al (1948) who transmitted the infection from a sheep to a human volunteer In most of these cases the lesions were on the skin of the hands or arms

The present case was confirmed by laboratory tests and is described not only because the site of the lesion was unusual, but also because there is reason to believe that human infections are less often recognised than their distribution and frequency warrant

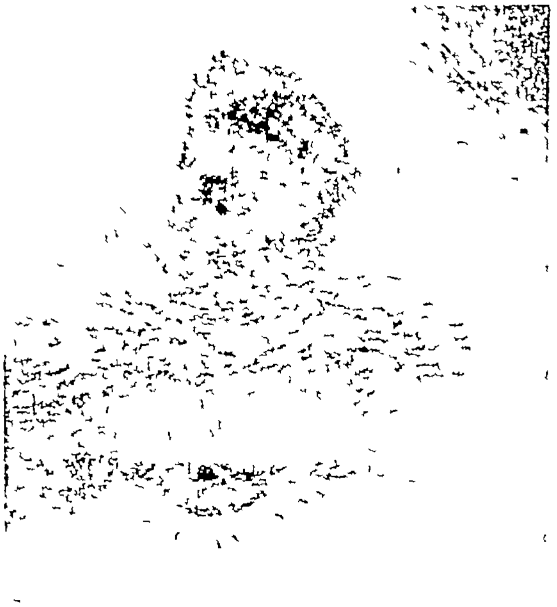

Fig 1—Lesion on brow caused by the virus of contagious pustular dermatitis

CLINICAL ACCOUNT

A pupil farmer, aged 21, worked on a lowland mixed farm but had recently helped in sheep rearing The flock was not known to be infected with orf, but the disease was subsequently confirmed by a veterinary colleague Early in August, 1950, the patient complained of a small vesicular swelling on the left side of the brow, which had started some days previously as a small red papule Within 48 hours the surface had flattened and increased in area During the next three days it grew to about ½ in in diameter and the surface of the vesicle thickened The patient said there had been no escape of fluid , and at this stage material was collected with sterile precautions by Dr W H J Baker, pathologist, Public Health Laboratory Service, Hereford, and sent to the department of bacteriology at Liverpool University

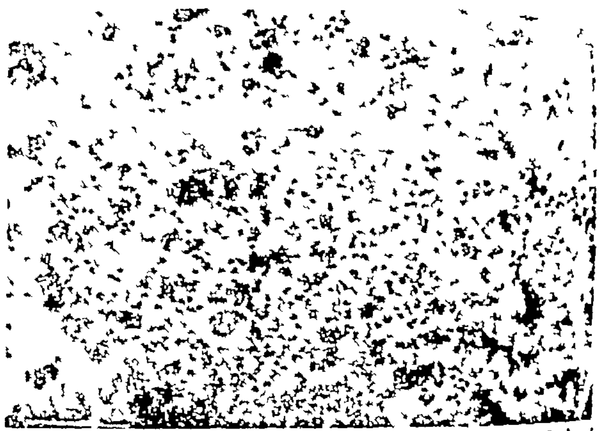

Fig 2—Elementary bodies in smear from C.P D lesion. Stained Gutstein (× 1500)

The lesion was essentially a flat topped vesicle with raised indurated edges and containing a clear exudate Later it became pustular but by this time it had been opened and there was opportunity for secondary invasion The patient then developed pre auricular adenitis There was little constitutional upset though orbital œdema produced a mild headache He was apyrexial when first seen, but after the lesion became pustular he had an occasional temperature of 99°F Thereafter an eschar was rapidly formed and the adjacent œdema decreased The photograph (fig 1) was taken 8 days after his first attendance at the surgery The eschar was difficult to remove and appeared to be embedded in an excessive growth of epithelial tissue The underlying ulcer showed raised edges and a granulomatous border

Two weeks after collecting the fluid for examination the œdema and induration had subsided but the scar and gross scaling were still prominent Two months after the original examination the affected part of the brow showed hyperæmia and desquamation but no evidence of scarring

At first the lesion caused some irritation but it became painless as it increased in size There was no history of minor injury to the brow before it developed

LABORATORY INVESTIGATIONS

Smears on glass slides of the serous fluid within the lesion, and a part of tissue from the edge of the lesion were available for examination The smears were stained by Gutstein's method but the specimens contained much cell debris and it was not possible to say whether or not virus was present The piece of tissue was ground in a mortar with powdered glass and extracted in a small volume of broth saline The supernatant fluid from the ground tissue suspension was cultured on blood agar Because of a scanty growth of *Staphylococcus albus* 50 units of penicillin per ml were added before further tests were undertaken Some of this fluid was then

inoculated on to the chorioallantois of developing chick embryos, but only ill defined lesions developed after 3 days' incubation, and further egg passage was negative The remainder of the fluid was rubbed into linear scarifications on the loin of a sheep The animal developed a typical infection with the formation of vesicles along the line of scarification on the 4th day Smears made from the base of one vesicle on the 6th day after inoculation were stained by Gutstein's method These showed large numbers of minute particles of identical size and appearance, and many of them were associated with damaged host cells A typical field is shown in fig 2, and the particles are indistinguishable from those seen in stained smears made from the base of vesicles in cases of smallpox Smears of the same material stained by Gram did not reveal any bacteria

Histological examination of sections from the edge of one vesicle showed epithelial proliferation and reticular degeneration, but inclusion bodies were not found Material from these lesions was also inoculated into eggs, but the virus did not produce lesions after the first egg passage

Cross immunity Experiments

CONTAGIOUS pustular dermatitis, or orf, is an infectious disease of sheep which is common in most sheep raising areas of this and other countries Affected animals develop a vesiculopapular eruption usually confined to the lips and surrounding tissue, but, in the severe form, lesions may also be present on the oral mucosa and on various other non wool bearing parts of the body The disease is prevalent in spring and summer and weaned lambs up to a year old are highly susceptible Aynaud (1923) showed that the disease is caused by a virus and this was confirmed by Glover (1928), who transmitted the infection with Berkefeld V filtrates of scrapings from infected animals to normal lambs Glover also showed by cross immunity tests that different sheep strains were immunologically identical

Veterinary surgeons and some physicians have long suspected that human infection was possible with the virus of contagious pustular dermatitis (C P D), but in most reported cases the evidence is circumstantial Thus Peterkin (1937) described five cases, but he did not demonstrate virus in the human lesions In the U S A, however Newsom and Cross (1934) transmitted infection from a human case to sheep but did not confirm its nature In Australia, Carne et al (1946) described three cases in which the nature of the lesions was investigated by infecting normal sheep from human material and by cross immunity tests There can be little doubt about the diagnosis in the patient described by Blakemore et al (1948) who transmitted the infection from a sheep to a human volunteer In most of these cases the lesions were on the skin of the hands or arms

The present case was confirmed by laboratory tests and is described not only because the site of the lesion was unusual, but also because there is reason to believe that human infections are less often recognised than their distribution and frequency warrant

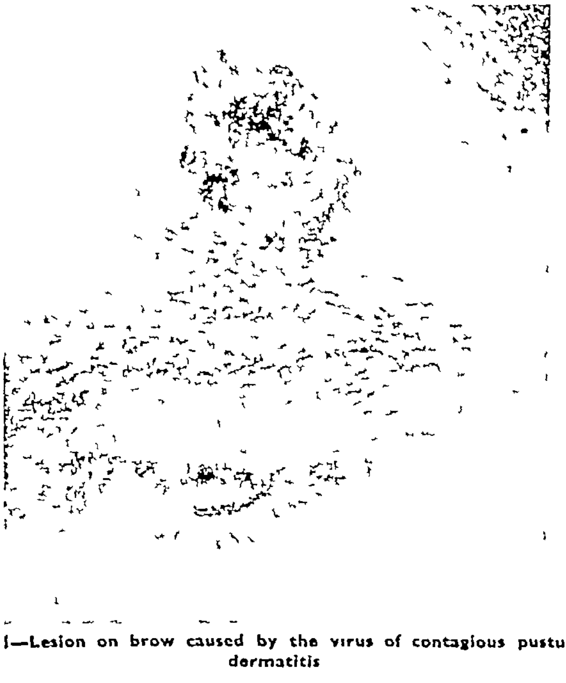

Fig 1—Lesion on brow caused by the virus of contagious pustular dermatitis

CLINICAL ACCOUNT

A pupil farmer, aged 21, worked on a lowland mixed farm but had recently helped in sheep rearing The flock was not known to be infected with orf, but the disease was subsequently confirmed by a veterinary colleague Early in August, 1950, the patient complained of a small vesicular swelling on the left side of the brow, which had started some days previously as a small red papule Within 48 hours the surface had flattened and increased in area During the next three days it grew to about $^1/_2$ in in diameter and the surface of the vesicle thickened The patient said there had been no escape of fluid, and at this stage material was collected with sterile precautions by Dr W H J Baker, pathologist, Public Health Laboratory Service, Hereford, and sent to the department of bacteriology at Liverpool University

Fig 2—Elementary bodies in smear from C P D lesion Stained Gutstein (× 1500)

The lesion was essentially a flat topped vesicle with raised indurated edges and containing a clear exudate Later it became pustular but by this time it had been opened and there was opportunity for secondary invasion The patient then developed pre auricular adenitis There was little constitutional upset though orbital œdema produced a mild headache He was apyrexial when first seen, but after the lesion became pustular he had an occasional temperature of 99°F Thereafter an eschar was rapidly formed and the adjacent œdema decreased The photograph (fig 1) was taken 8 days after his first attendance at the surgery The eschar was difficult to remove and appeared to be embedded in an excessive growth of epithelial tissue The underlying ulcer showed raised edges and a granulomatous border

Two weeks after collecting the fluid for examination the œdema and induration had subsided but the scar and gross scaling were still prominent Two months after the original examination the affected part of the brow showed hyperæmia and desquamation but no evidence of scarring

At first the lesion caused some irritation but it became painless as it increased in size There was no history of minor injury to the brow before it developed

LABORATORY INVESTIGATIONS

Smears on glass slides of the serous fluid within the lesion, and a part of tissue from the edge of the lesion, were available for examination The smears were stained by Gutstein's method but the specimens contained much cell debris and it was not possible to say whether or not virus was present The piece of tissue was ground in a mortar with powdered glass and extracted in a small volume of broth saline The supernatant fluid from the ground tissue suspension was cultured on blood agar Because of a scanty growth of *Staphylococcus albus* 50 units of penicillin per ml were added before further tests were undertaken Some of this fluid was then

Brockman et al (1950) have described the synthesis and isolation in crystalline form, and the empirical formula, of a substance which they have produced from folic acid and which appears to have the same biological properties as those described for citrovorum factor derived from liver In 1949 Bond et al. reported the isolation from liver of a substance which they named "folinic acid," and which is probably the same as the citrovorum factor

A leading article in THE LANCET (1951) gives an excellent account of the historical aspects of these discoveries and the evidence for their relation to each other It also mentions the therapeutic response to folic acid of a megaloblastic anæmia induced in monkeys by dietary deficiency, and expresses the hope that reports on its action in human megaloblastic anæmia should soon be to hand. This preliminary report is accordingly submitted for publication

MATERIAL

The citrovorum factor used in this investigation was a product of biological origin kindly supplied to us by Dr T H Jukes, of Lederle Laboratories, Inc, Pearl River, N Y It was free from vitamin B_{12} and folic acid, and was prepared for parenteral administration in ampoules containing 20 million units of microbiological activity per ml It has recently been shown (Brockman et al. 1950) that about 0 15–0 20 mμg of the synthetic citrovorum factor corresponds to one "unit" of the biological product, and hence each millilitre of the preparation supplied to us contained the equivalent of approximately 3–4 mg of the synthetic citrovorum factor

METHOD

Three patients with addisonian pernicious anæmia were chosen In each case the dietary history was good, there was no diarrhœa, the test-meal showed histamine fast achlorhydria, and the marrow was megaloblastic

After a control period, during which there was no evidence of remission, the patients were given, respectively, 20, 40, and 80 million units of citrovorum factor in a single intramuscular injection, and the hæmatological response was followed for two weeks

The results are shown in the accompanying table It is evident that there was a slight hæmatological response in case 1 receiving 20 million units, and in case 2 where 40 million units was given and a good hæmatological response in case 3 where 80 million units was given A corresponding improvement in the state of well-being also occurred in case 3

DISCUSSION

These results suggest that provided a large enough dose is given, the *L citrovorum* factor will produce a hæmatological and clinical response in pernicious anæmia Since 80 million units of the citrovorum factor derived from biological sources contains the equivalent of approximately 12–16 mg of synthetic citrovorum factor, it would appear that the therapeutic dose in milligrammes of folic acid and citrovorum factor are of the same order This is to be contrasted with the therapeutically active dosage of vitamin B_{12}, which is measured in microgrammes rather than milligrammes

It is now known that the citrovorum factor can replace folic acid as a growth factor for *Streptococcus fæcalis* It is also known that the content of folic acid in refined liver extracts is of the order of a few micro grammes or less This figure represents not only the folic acid content but also the amount of *L citrovorum* factor in the liver extracts Accordingly it is certain that the activity of refined liver extract in the treatment of pernicious anæmia is not related to its content of either of these substances but to its content of vitamin B_{12}. The work of Nichol and Welch (1950) suggests that the *L citrovorum* factor may be the derivative of pteroylglutamic acid actually responsible for the continuation of normoblastic blood formation

SUMMARY

Three cases of addisonian pernicious anæmia have been treated with 20, 40, and 80 million biological units of citrovorum factor Only when 80 million units was given was a satisfactory response obtained

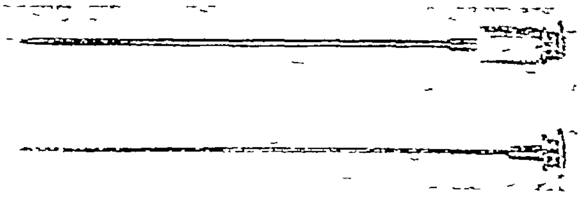
TROCHAR AND CANNULA FOR TAPPING LATERAL VENTRICLE

TAPPING the lateral ventricles is now an established procedure for both diagnostic and therapeutic purposes. Where it is necessary to drill a burr-hole in the skull the dura is usually nicked with a tenotomy knife and the ventricle tapped with a blunt-ended brain cannula In infants, however the ventricle can be reached without trephining the skull through the lateral corner of the anterior fontanelle The instrument here described has been designed for use in infants and for repeated ventricular tapping in older children in whom the skin over a previous burr-hole has healed

As this procedure is usually performed, the operator either incises skin and dura with a scalpel before inserting a brain cannula or more simply uses a lumbar-puncture needle for traversing skin, meninges, and brain substance The second method is not without risk because the sharp needle may cut through an intracerebral blood-vessel



The instrument illustrated consists of a fine cannula which may be fitted with a trochar or with a blunt obturator The Pannett's mount, which is Record fitting, is keyed to ensure that the trochar or obturator fits closely and does not rotate The end of the cannula is tapered slightly to make a smooth surface with the trochar or obturator, which just protrudes The instrument, which is graduated in centimetres from the distal end is made in two sizes 17 and 19 S W G, both 3 inches long (excluding mount)

Technique.—With the trochar in position the cannula is inserted through the skin and cautiously pushed onwards until the dura is pierced This is easily felt by the operator who then removes the trochar and replaces it with the blunt obturator before traversing the brain itself.

Our thanks are due to Mr A. W Woodhead of the Hospital for Sick Children, Great Ormond Street, who made the prototype and to Mr W A S Whittlesey of St Mary's Hospital for his help in designing the model here described The cannula is made by Messrs. Willen Bros, of 44 New Cavendish Street London, W 1

OSCILLATION OF THE EYES OF KITTENS KEPT IN THE DARK

Cat no	Litter no	Age (weeks)	Weeks in dark		Weeks to recover
			Before oscillations	No oscillations	
A	1	6	4		1
B			4		1
C			7		1
D	2	4	Died		
E			4		Died
F				8	Died

METHOD AND RESULTS

Three black kittens, aged 6 weeks, and three tabbies, aged 4 weeks, were placed in a completely dark room and observed every week with an ophthalmoscope Six brown rats and six black and white rabbits were treated in the same way None of the animals had oscillating eyes before being put in the dark, but oscillations were noted in three of the kittens after 4 weeks in the dark, and in a fourth after 7 weeks (see table) One kitten had no oscillations after 8 weeks in the dark In the black kittens (litter 1) the oscillations were rotary and there was a synchronous tremor of the head The oscillations were exaggerated on looking up and to the sides, comparable to what is noticed in coalminers' nystagmus On being put back into daylight all the kittens in litter 1 recovered within a week, but litter 2 died of an intercurrent infection before the experiment was finished A close up cinematograph film of the oscillating eyes of kittens A and B was taken, and again of kitten B when its eyes had recovered None of the rats or rabbits showed oscillations even after 7 months in the dark

DISCUSSION

The Miners' Nystagmus Committee (1922) cited Ohm (1916) as having kept three puppies and two kittens in a dark cellar and as finding nystagmus in all of them after an interval of 10–48 days This observation seems never to have been confirmed or definitely demonstrated since then Ohm, at that date, could only use a mechanical recording method, in which a lever pressed directly on the eyeball and drew a tracing on a kymograph drum He also found that light had a " calming " influence on the oscillations The present pilot experiment confirms and records this fundamental observation

Riesen (1947, 1950) produced nystagmus in chimpanzees, which have a visual apparatus almost identical to that of man, by rearing them in the dark from birth before they had time to develop binocular vision One of his chimpanzees developed an external squint, and another an internal squint, comparable to the convergence so often seen in coalminers' nystagmus One chimpanzee had attacks of nystagmus when it was excited, closely comparable to a patient recently seen who complained of the oscillations " when he was vexed " Riesen's final experiment was to put a chimpanzee, aged 7 months (when it had developed its full visual functions), into the dark, and it too developed nystagmus and became unable to recognise surrounding objects This perhaps suggests that coalminers' nystagmus may well be a partial disuse atrophy of the visual function from lack of light Moreover Browne and others (1950) have shown that coalminers with nystagmus differ very little from those without it, and that the psychological symptoms are the result, rather than the cause, of the disability

SUMMARY

Four out of six kittens developed rotary nystagmus after being kept in the dark 4–7 weeks Three of the four recovered after being in daylight for a week

A close up cinematograph film recorded the results

These findings confirm the results of experiments made by Ohm (1916) on puppies and by Riesen (1947, 1950) on chimpanzees

They suggest that coalminers' nystagmus may be a type of disuse atrophy of the visual apparatus

Acknowledgments are due to the National Coal Board for a grant towards the expense of this work.

Preliminary Communication

TREATMENT OF PERNICIOUS ANÆMIA WITH LEUCONOSTOC CITROVORUM FACTOR

In recent years there have been numerous reports about the activity of pteroylglutamic acid (folic acid) and of vitamin B_{12} in the treatment of the megaloblastic anæmias The purpose of this paper is to report on the hæmopoietic activity in pernicious anæmia of yet another factor that has been isolated from liver

Sauberlich and Baumann (1948) showed that certain natural materials, including liver, liver extracts, and yeast extracts, contain a growth factor for the streptococcus—*Leuconostoc citrovorum* This factor, which they called the " citrovorum factor," differs from vitamin B_{12} in that it can be separated from the latter by electrolysis (Lyman and Prescott 1949), and because pure vitamin B_{12} will not stimulate the growth of *L citrovorum* (Scheid and Schweigert 1950) It also differs from folic acid in certain *growth promoting* activities for bacteria (Sauberlich and Baumann 1948)

Penicillin Dosage

THE ultimate aim of antibiotic therapy is to cure the patient as quickly and comfortably as possible The planning of treatment may present no difficulties, but in serious cases it often calls for close liaison between clinician and pathologist, and for some understanding of drug actions and the defence mechanisms of the tissues To treat every case with the latest antibiotic is an impressive but unjustifiably costly practice, nor should one look on one drug as "the best" for pneumonia, another for meningitis, and a third for cystitis—the action of antibiotics is specific for infecting micro organisms, not for clinical syndromes However, in an acute infection a day's delay in starting treatment may mean irreparable damage, so antibiotic treatment should be started as soon as the material needed for isolating the infecting organism has been collected When the pathogen has been identified and its drug sensitivity determined, the clinician applies his knowledge of therapeutics to these findings to obtain the best results Some drugs, like the sulphonamides and perhaps the newer antibiotics, are more bacteriostatic than bactericidal, treatment with these should therefore be continued long enough to allow the host's tissues to play their full part in overcoming the infection, though not unnecessarily long because of the risk of sensitisation and other drug reactions Penicillin and streptomycin are known to be bactericidal in optimal concentrations, and they are therefore particularly useful drugs when the host's reaction is poor, as in the bronchopneumonias of the very young and the very old

Most antibiotics are effective only against bacterial cells that are actively growing, and some relapses have been ascribed to the survival of resting organisms —"persisters," as BIGGER calls them—which begin to multiply again when the course of antibiotic is finished. For this and other reasons, some authorities advocate the administration of penicillin, in a dosage or preparation which will produce a high intermittent blood-penicillin level rather than a low sustained one The merits of the two procedures were compared, on the basis of laboratory work, by EAGLE[1] and MARSHALL,[2] and they are admirably summarised by BEYER[3] in his new book on the pharmacology of penicillin. EAGLE and his colleagues[4] contend, from their findings in experimental streptococcal, pneumococcal and syphilitic infections in rabbits and mice, that the factor on which the therapeutic activity of penicillin mainly depends is the aggregate time, not necessarily continuous, during which a bactericidal level exists in the blood But the concentration of penicillin in the infected lesion may not bear any close relation to the blood level, for the drug passes more slowly into inflamed than into normal tissue and the drug concentration attained in inflamed tissue is usually lower than the blood level, moreover, if the lesion is poorly vascularised or walled off by a fibrinous barrier, as in bacterial endocarditis and staphylococcal abscesses, the blood-level will have to be many times the minimum effective in-vitro level before enough of the drug will seep into the lesion to produce a bactericidal concentration We must remember, too, that the laboratory test measures the *bacteriostatic* concentration, which for penicillin may be well below the *bactericidal* level required to destroy bacteria in infected tissues The concentration of penicillin to which an organism has been exposed and the duration of that exposure affect the time required for the bacteria to recover both in vitro and in vivo Any attempts to estimate the interval that may safely be allowed between doses of penicillin must take into account the wide differences in the rate of multiplication of bacteria (20–30 minutes for the pyogenic cocci, and 18–24 hours for the tubercle bacillus and *Treponema pallidum*), the variable time required by different bacteria to recover from the toxic effects of penicillin, and the variable number of organisms to be destroyed.

Such considerations do not necessarily justify the massive dosage of penicillin that has become routine practice today, for, provided the drug has ready access to the lesion, a serum level only two to four times that required to kill micro organisms at the maximum rate in vitro will be equally effective in vivo, and though massive dosage may multiply this serum level by several hundred it will not accelerate the rate of killing On the other hand, a daily dose of procaine penicillin which maintains a fairly constant low blood-level may not produce a concentration of penicillin in the diseased tissues high enough or for long enough to be bactericidal in staphylococcal pyæmia or more chronic infections like subacute bacterial endocarditis and actinomycosis Even fortification with crystalline penicillin may not help unless it is given in very large doses, because its action is too evanescent There is, however, good experimental and clinical evidence that intermittent penicillin therapy with infrequent doses is effective in various infections, and on this evidence greater use might be made of penicillin by mouth, given on an empty stomach twice a day in amounts 5-10 times the parenteral dose This method is suitable for adults as well as for babies and older children,[5] and it is particularly convenient in general practice, its wider adoption would save doctors' and nurses' time and hospital beds, besides lessening the patient's discomfort Penicillin's toxicity is low, but it retains some allergenic propensity even when purified, and for this reason the clinician may prefer a brief but unstinting dosage to a more sparing and protracted one The best way to save expense is by re educating the young doctor and some of his senior colleagues in the value of sulphonamides, keeping the more expensive antibiotics for conditions which really demand them A note on p 750 shows how costly these drugs can be

Reviews of Books

The Abnormal Pneumoencephalogram

LEO M DAVIDOFF, M D, clinical professor of neurosurgery, New York University, BERNARD S EPSTEIN, M.D, associate radiologist, The Jewish Hospital of Brooklyn, N Y London Henry Kimpton 1950 Pp 506 £5 5s

THIS book is the sequel promised in *The Normal Encephalogram* which Professor Davidoff wrote in collaboration with Dr Cornelius Dyke, whose early death in 1943 caused postponement of the projected book on air studies of the abnormal brain Dr Bernard Epstein has joined Professor Davidoff on the neuroradiological side, and the volume has been much enlarged by comparison with what was originally proposed It will certainly become a standard reference work, and the large amount of case-material will interest neurologists and neurosurgeons as well as radiologists

Through analysis of the changes in outline produced by space occupying lesions in various sites, the authors proceed to consideration of the changes caused by atrophic and other lesions of the brain and meninges Each chapter is divided into a brief clinical survey, a thorough survey of previous literature, some well presented and well illustrated case material, and a summary of findings with a discussion on differential diagnosis

The radiographic technique employed seems to rely on relatively complete replacement of cerebrospinal fluid by air, in that many of their illustrations show projections obtained with the head in the lateral position In some cases projections with the head in the brow up or brow down position, using the technique described by Lysholm, might have demonstrated the lesions more convincingly, particularly in the chapters on the temporal horn and on neoplasms of the corpus callosum In the chapter on neoplasms of the lateral ventricles there is a failure to differentiate clearly between neoplasm arising from the ventricular wall and the invading neoplasm, and the films reproduced to illustrate agenesis of the corpus callosum might have been better These, however are small defects in a book which is a worthy companion to its forerunner

The Cytologic Diagnosis of Cancer

Staff of the Vincent Memorial Hospital, Department of Gynecology, Harvard Medical School Philadelphia and London W B Saunders 1950 Pp 229 33s

THIS book, devoted to the diagnosis of cancer by smear techniques, using the method of Papanicolaou, describes fully the applications of the method to cells exfoliated from various mucous membranes, or present in serous exudates Nearly half the volume is concerned with the female genital tract, and this section is profusely illustrated, in atlas form, with different combinations of photographs and drawings (some in colour) accompanied by diagrammatic keys These illustrations demonstrate clearly the different types of cells encountered in normal and pathological conditions of the genital tract The remaining chapters deal more briefly with the respiratory tract, stomach, pleural and peritoneal fluids, and urinary tract, including the prostate Even with such aids as this it cannot be concluded that accurate diagnosis by the Papanicolaou technique is achieved save by long-continued observation and experience, but for those who are resolved to embark on this hazardous enterprise this book should be indispensable

A Surgeon's Fight to Rebuild Men

FRED ALBEE, M D London Robert Hale 1950 Pp 270 15s

Dr Albee's account of his fight is addressed to the general public in terms which they can well understand It is a story of success, related by the author with gusto and becoming modesty He tells how even his childhood experiences were turned to good account His grandfather, at work in the orchard, taught the little boy the first principles of successful grafting Before he was ten years old he had made for himself a tiny water driven rotary saw, the forerunner of the famous Albee bone mill to which can be fitted the tools used in the precise shaping and adaptation of the bone graft—saws drills, die cutters, chisels, and files Before he was forty he was invited to demonstrate his instrument at the 17th conference of the International Association of Medicine and Surgery, held in London in 1913 In two great wars he perfected his methods, relying always, as he explains, on the phenomenal power of bone to regenerate The most slender graft, in a long bone, if successfully implanted, will always grow to that thickness which is necessary to bear the strain to which it is subjected

Successful results in orthopædic surgery are visible not only to the delighted patient but to the eye of every onlooker The photograph, before and after, proclaims the marvel even to the uninitiated Perhaps only the *plastic surgeon of the face enjoys an equal share of* public appreciation Workers in both these fields are apt to find themselves more than ordinarily liable to be hailed as miracle-workers and as benefactors of humanity, but in Dr Albee's case the claim will not be disputed

The Enzymes

Chemistry and Mechanism of Action Vol I, part 1 Editors JAMES B SUMNER, Laboratory of Enzyme Chemistry, Cornell University, New York, KARL MYRBÄCK, Institute for Organic Chemistry and Biochemistry, University of Stockholm New York Academic Press 1950 Pp 724 $13 50

THIS treatise, the scope of which is correctly described by the publishers as "encyclopædic," will appear in four parts, of which this is the first Since C Oppenheimer's *Die Fermente*, published 25 years ago, nothing like this book has appeared The work of 78 leading specialists is to be incorporated in the four parts, and *the whole subject—not only* recent advances—will be covered This first part contains an introduction to enzymology, in eight general chapters, and three fascinating long sections—on enzymes in relation to genes viruses, hormones, vitamins, and chemotherapy, on the *cytochemical foundations of enzyme* chemistry, and on enzymatic adaptation—in which recent activity is well surveyed L Massart contributes a chapter on enzyme inhibition, and J R Marrack, of the London Hospital, an excellent review of enzymes and immunology Chapters on special enzymes cover esterases, cholinesterase, sulphatases, invertase, glucosidases, and glucuronidase, and end with an informative review of amylases by K Myrbäck and G Neumüller The book will undoubtedly become a standard reference work.

Collected Papers on Psychoanalysis

ELLA FREEMAN SHARPE Editor MARJORIE BRIERLEY London Hogarth Press and Institute of Psychoanalysis 1950 Pp 280 21s

Miss Sharpe was a gifted expositor of psycho analysis, as this collection shows The papers fall into three groups on technique, on theory, and on literary interpretation The seven lectures on technical matters are lucid and obviously based on much experience Studies of sublimation in art and science, and the development of metaphor as an outcome of the control of bodily orifices, lead the reader into territory which, if he is not a psycho analyst, he may well view with sceptical eye, especially when he meets a familiar phrase seemingly misquoted or misheard (as in 'I wouldn't touch her with a branched pole') More in keeping with Miss Sharpe's gifts and earlier training are the literary studies with which the book ends These examine the imagery of Francis Thompson's poetry, the impatience which Hamlet shows (in contrast to the procrastination commonly stressed in his character and behaviour), and some inferences about Shakespeare's life which can be drawn from *King Lear* by an alert and ingenious psycho analyst

---

A Doctor Remembers (London Seeley Service & Co 1950 Pp 288 12*s* 6*d*)—Many an elderly reader, taking up Dr E A Barton's autobiography, will wish he could have had it by him when he was a young doctor The whole of his medical life might have been altered No one could be a more frank and reliable guide than Dr Barton for the fifth year student or the houseman—though not everybody will agree with his views on euthanasia Kindliness, charity, wit, and humour fill his pages no rushing the patient to the operating theatre, *ohne Hast, ohne Rast, immer langsam voran* is a good dictum Plain ("scout") radiographs of the abdomen, with the patient supine and erect, should invariably be taken These will demonstrate the cæcum, which serves as the wind sock—the guide to the surgical line of approach—and also clinches the diagnosis of large bowel obstruction The volvulus will be clearly outlined, and the small intestine obstruction will be evident in the parallel loops and multiple fluid pools Moreover, as Mr RODNEY SMITH emphasised, in many cases the ileocæcal valve holds, forming a closed obstruction loop which only operation can relieve, when this valve is incompetent, ballooning of the small intestine is evident on the radiograph The surgeon may then be tempted to introduce a Miller-Abbott tube, but every speaker agreed that this may lose valuable time, for the tube cannot decompress the large bowel and its passage through the pylorus is unpredictable Passage of a Ryle tube is always necessary, and the anæsthetist must take precautions against regurgitation Fluid replacement is called for, as Mr H E LOCKHART-MUMMERY remarked, but this therapy has to be tempered with fine judgment, particularly in the old Awareness of the hazards of intravenous therapy is now more acute (It has been well declared that more people have been drowned on the banks of the Thames than in it) The saline content of the urine is a sensitive indicator of salt need, and should become a standard ward test Mr E W GRAHAME recommended that if the chloride test is positive, 0 45% saline should be infused, and this should be followed with plasma or even blood.

As to the surgical procedure, opinion differed little Cæcostomy, blind or otherwise, was regarded as less satisfactory than transverse colon loop colostomy, preferably through a transverse abdominal incision This affords more effective rapid decompression, and the more complete "defunctioning" is a great advantage in the subsequent stage of resection Some wag, talking of visceroptosis, has suggested that "where a man wears his guts is his own business", but in large-bowel obstruction it is very much the surgeon's concern Fat patients very often have short mesenteries, and, as Mr H R THOMPSON said, the obstructed colon, tethered by its mesentery, expands between the leaves, shortening it even more Delivery of such a colostomy to the surface may thus be difficult or impossible, and the surgeon is sometimes forced to do a cæcostomy This may be difficult If spilling is to be avoided, the bowel should be punctured with a fine needle and then cleared with trochar-puncture suction, after suitable packing and purse string suture, satisfactory decompression will be achieved only with drainage through a large tube and exteriorisation of the bowel. Cæcostomy may also be advisable for growths of the splenic flexure, for in the subsequent resection the surgeon is not handicapped by an otherwise fixed transverse colon Even the obstructing transverse colon growth is probably better handled in this way than by immediate resection on an area of œdematous mesentery Pelvic colon colostomy is to be avoided, it embarrasses the surgeon in any subsequent resection

Should the abdomen be gently explored at the same time? Obviously the surgeon will be guided by the amount of bowel distension Professor MORLEY suggested that with the anæsthetist's use of muscle relaxants (spinal anæsthetics are hazardous) this was now often possible, and it provided the surgeon with reasonable information for planning further procedures Mr RODNEY SMITH, however, felt that this procedure was dangerous, and from the patient's angle often merely morbid curiosity Mr LOCKHART-MUMMERY, who described a study of some 90 case-records collected from five different hospitals, gave examples showing that what seemed an inoperable growth on palpation by this method was often merely due to secondary inflammatory changes Even with secondary growths in the liver, most surgeons now endeavour to remove subsequently the primary growth, and these patients often live for three years in relative comfort [4] Immediate resection and anastomosis, as any surgical tyro knows, has no place in this type of surgery The Paul-Mikulicz procedure though it has a deservedly good reputation in mild subacute obstruction, should not be undertaken here, for it does not safely afford the necessary wide mobilisation of the bowel. Obstruction of the right colon, it was also generally agreed, is preferably dealt with by lateral ileocolic anastomosis rather than ileostomy, which might lead to skin excoriation and a distressing convalescence Such anastomosis needs very fine close stitching if leakage is to be avoided, the anastomosis should be placed some twelve inches from the ileocæcal valve and joined to the mid transverse colon. Primary hemicolectomy is occasionally permissible, Professor MORLEY recommends in addition E G MUIR's manœuvre of passing a drainage tube through the colon end and via the stoma into the ileum

In the immediate aftercare the electrolyte balance will need attention. House-surgeons to whom drips are delegated should be warned, for otherwise they will not tiptoe as the experienced surgeon does, appreciating more fully the complex physiological issues Increased significance is now attached to the potassium ion [5], and Mr GRAHAME pointed out that the potassium values were high in these cases, probably owing to circulatory failure and associated renal insufficiency The effects of parenteral potassium on the myocardium may be serious, so at least three conditions must be met there must be a daily urinary output of over 750 ml, and each day an electrocardiogram must be taken and the serum potassium level recorded [6] Three weeks seems to be ample time for resolution of the colon œdema and ulceration, and for the wall blood supply to become fit for resection of the bowel End-to end anastomosis is to be preferred, though there is room for personal choice The so called aseptic anastomosis, as Professor MORLEY emphasised, is of no particular advantage at this stage The method of closing colostomies needs further thought by the surgeon This may be a difficult procedure, with occasional deaths The present practice of enterotome-crushing of the spur in the Paul Mikulicz procedure is surely an anachronism Closure of large numbers of colostomies in the belly wounds of war has convinced many surgeons that excision of the

Treatment of Depression

If, among the many who attended the discussion on depression at the Royal Society of Medicine on March 13, there was anyone who came to see the psychological and somatological schools of psychiatry in open combat, he must have been disappointed Since 1936 Dr **Clifford Scott**, the representative of psycho analysis, has treated selected patients with affective psychoses by the methods of Freudian analysis but in such cases he still regards this treatment as experimental and full of difficulties and dangers Moreover, during analysis he has observed faints, drowsiness, amnesia, attacks of rage and furor, and sudden suicidal urges—in short, symptoms reminiscent of epilepsy, pointing, he thinks, to an instinctive yearning by the patient for " shock " and convulsive treatment He also found that previous convulsive treatment was helpful to the progress of analytical procedure The number of beneficial results he could quote from psycho analysis alone, was not impressive , but his critical and persistent endeavour to unravel the psychopathology of melancholia in the footsteps of **Abraham** command respect

Dr **Scott** was preceded by Dr W **Mayer Gross**, who began by pointing out the change in therapeutic approach to the affective psychoses within the last fifteen years, through the introduction of convulsive therapy He thought it necessary, however, to recapitulate long established measures Some of these, such as the avoidance of suicidal risks, have in a modified form become more important with the new treatment , others, such as the combating of anorexia, loss of weight, and constipation—formerly the most hazardous tasks in treating depression—hardly present any problem nowadays Depressive illness is still often mistaken for physical disease , and the patient may be treated for gastro intestinal complaints, anæmia, pulmonary tuberculosis, or malignant disease But even if the patient's bodily health is greatly impaired during lengthy investigations before he sees a psychiatrist, once the diagnosis is made a few convulsions will restore all bodily functions, including sleep, before the psychological effect becomes very obvious Wisely used, electrically induced convulsion treatment can transform the outlook of a depressive attack , and the most common mistake, according to Dr **Mayer Gross**, is its excessive and indiscriminate use Of all the affective syndromes, involutional depression derives most benefit from convulsion treatment A series of 100 depressive patients over the age of forty, without earlier history of depression, were followed up for two to nine years after being treated at Crichton Royal between 1940 and 1947 At the time of the follow up, 72 were fully recovered, 6 socially recovered, and 11 home invalids , only 3 had had to remain in hospital all the time There had been 8 deaths, 2 by suicide In an equal group of younger manic depressive patients with definite recurrent attacks, the response to convulsive therapy was not so definite , but, despite a larger proportion of relapses, a shortening of suffering and of hospital care was usually apparent The rhythm of the illness and the number of attacks was, however, not influenced by the convulsive treatment

In the general discussion great interest was shown in the type of case that totally or partially resists convulsion therapy Most speakers agreed on its failure in younger patients in whom severe anxiety is associated with depression Opinion was divided on its suitability in reactive depression—i.e , in patients with an acute or chronic conflict situation probably responsible for the depressive illness Dr G **Garmany**, the third opener, who dealt mainly with the important use of electric convulsions in outpatient clinics, illustrated his points with some statistics from Westminster Hospital He found the treatment worth while and efficient in reactive depressions, provided the premorbid personality was stable and not of a psychopathic type Little was said about leucotomy in depressive states except for some cautionary counsel that it may destroy the delicate emotional responses which are the great asset of the cyclothymic patient Only for those cases of manic depression in which psychotic attacks follow one another so quickly that the patient has to stay permanently in hospital, is operative treatment indicated , and less damaging and more exactly localised neurosurgical techniques should be sought for such cases

Carcinomatous Obstruction of the Colon

Medicine is advancing so swiftly at so many points that any slower progress seems disappointing The mortality from acute obstruction of the colon due to malignant disease is a good example of this slower tempo In the '30s the operative mortality was about 30% , and since then, despite antibiotics, intestinal antiseptics, and other innovations, it has fallen only to some 18–20% By contrast, the mortality of operations on uncomplicated carcinoma of the colon has fallen strikingly The figures of **Allen** et al[1] indicate a fall from 17 5% to under 2% , and indeed it is reasonably contended that " barring accidents . . , the surgeon may be reasonably confident that his patient will survive such uncomplicated colon resection "[2]

At the Royal Society of Medicine on March 7, Prof **John Morley**, opening a discussion on large bowel obstruction due to malignant disease, urged the need for clear instructions to registrars, who are most commonly required to cope with this emergency Nevertheless the greatest skill may not suffice, for obstruction of this sort is often a late complication, and the patient may arrive with the bowel already perforated , moreover many of these patients have what **Samuel Johnson** termed the most incurable of all diseases—old age Obstruction does not usually come without warning , diarrhœa, with mucus in the stools, and colicky pain drive most patients into seeking advice Occasionally, however, as Mr **Rodney Smith** pointed out, the doctor may be deceived by the complaint of right sided abdominal pain, due to cæcal distension or mobility of a distended sigmoid loop[3] In 90% of cases the obstruction—usually of the ' napkin ring " type—is in the left colon , and involvement of the right colon nearly always indicates an advanced growth There must be no rushing the patient to the operating-theatre , *ohne Hast, ohne Rast, immer langsam voran* is a good dictum Plain (' scout ") radiographs of the abdomen, with the patient supine and erect, should invariably be taken These will demonstrate the cæcum, which serves as the wind-sock—the guide to the surgical line of approach—and also clinches the diagnosis of large bowel obstruction The volvulus will be clearly outlined , and the small intestine obstruction will be evident in the parallel loops and multiple fluid pools Moreover, as Mr **Rodney Smith** emphasised, in many cases the ileocæcal valve holds, forming a closed obstruction loop which only operation can relieve , when this valve is incompetent, ballooning of the small intestine is evident on the radiograph The surgeon may then be tempted to introduce a Miller Abbott tube, but every speaker agreed that this may lose valuable time , for the tube cannot decompress the large bowel, and its passage through the pylorus is unpredictable Passage of a Ryle tube is always necessary, and the anæsthetist must take precautions against regurgitation Fluid replacement is called for, as Mr H E **Lockhart-Mummery** remarked , but this therapy has to be tempered with fine judgment, particularly in the old Awareness of the hazards of intravenous therapy is now more acute (It has been well declared that more people have been drowned on the banks of the Thames than in it) The saline content of the urine is a sensitive indicator of salt need, and should become a standard ward test Mr E W **Grahame** recommended that if the chloride test is positive, 0 45% saline should be infused, and this should be followed with plasma or even blood

Treatment of Depression

IF, among the many who attended the discussion on depression at the Royal Society of Medicine on March 13, there was anyone who came to see the psychological and somatological schools of psychiatry in open combat, he must have been disappointed Since 1936 Dr CLIFFORD SCOTT, the representative of psycho analysis, has treated selected patients with affective psychoses by the methods of Freudian analysis, but in such cases he still regards this treatment as experimental and full of difficulties and dangers Moreover, during analysis he has observed faints, drowsiness, amnesia, attacks of rage and furor, and sudden suicidal urges—in short, symptoms reminiscent of epilepsy, pointing, he thinks, to an instinctive yearning by the patient for "shock" and convulsive treatment He also found that previous convulsive treatment was helpful to the progress of analytical procedure The number of beneficial results he could quote from psycho analysis alone, was not impressive, but his critical and persistent endeavour to unravel the psychopathology of melancholia in the footsteps of ABRAHAM command respect

Dr SCOTT was preceded by Dr W MAYER GROSS, who began by pointing out the change in therapeutic approach to the affective psychoses within the last fifteen years, through the introduction of convulsive therapy He thought it necessary, however, to recapitulate long established measures Some of these, such as the avoidance of suicidal risks, have in a modified form become more important with the new treatment, others, such as the combating of anorexia, loss of weight, and constipation—formerly the most hazardous tasks in treating depression—hardly present any problem nowadays Depressive illness is still often mistaken for physical disease, and the patient may be treated for gastro intestinal complaints, anæmia, pulmonary tuberculosis, or malignant disease But even if the patient's bodily health is greatly impaired during lengthy investigations before he sees a psychiatrist, once the diagnosis is made a few convulsions will restore all bodily functions, including sleep, before the psychological effect becomes very obvious Wisely used, electrically induced convulsion treatment can transform the outlook of a depressive attack, and the most common mistake, according to Dr MAYER-GROSS, is its excessive and indiscriminate use Of all the affective syndromes, involutional depression derives most benefit from convulsion treatment A series of 100 depressive patients over the age of forty, without earlier history of depression, were followed up for two to nine years after being treated at Crichton Royal between 1940 and 1947 At the time of the follow up, 72 were fully recovered, 6 socially recovered, and 11 home invalids, only 3 had had to remain in hospital all the time There had been 8 deaths, 2 by suicide In an equal group of younger manic depressive patients with definite recurrent attacks, the response to convulsive therapy was not so definite, but, despite a larger proportion of relapses, a shortening of suffering and of hospital care was usually apparent The rhythm of the illness and the number of attacks was, however, not influenced by the convulsive treatment

In the general discussion great interest was shown in the type of case that totally or partially resists convulsion therapy Most speakers agreed on its failure in younger patients in whom severe anxiety is associated with depression Opinion was divided on its suitability in reactive depression—i.e, in patients with an acute or chronic conflict situation probably responsible for the depressive illness Dr G GARMANY, the third opener, who dealt mainly with the important use of electric convulsions in outpatient clinics, illustrated his points with some statistics from Westminster Hospital He found the treatment worth while and efficient in reactive depressions, provided the premorbid personality was stable and not of a psychopathic type Little was said about leucotomy in depressive states except for some cautionary counsel that it may destroy the delicate emotional responses which are the great asset of the cyclothymic patient Only for those cases of manic depression in which psychotic attacks follow one another so quickly that the patient has to stay permanently in hospital, is operative treatment indicated, and less damaging and more exactly localised neurosurgical techniques should be sought for such cases

Carcinomatous Obstruction of the Colon

MEDICINE is advancing so swiftly at so many points that any slower progress seems disappointing The mortality from acute obstruction of the colon due to malignant disease is a good example of this slower tempo In the '30s the operative mortality was about 30%, and since then, despite antibiotics, intestinal antiseptics, and other innovations, it has fallen only to some 18–20% By contrast, the mortality of operations on uncomplicated carcinoma of the colon has fallen strikingly The figures of ALLEN et al.[1] indicate a fall from 17 5% to under 2%, and indeed it is reasonably contended that "barring accidents the surgeon may be reasonably confident that his patient will survive such uncomplicated colon resection"[2]

At the Royal Society of Medicine on March 7, Prof JOHN MORLEY, opening a discussion on large bowel obstruction due to malignant disease, urged the need for clear instructions to registrars, who are most commonly required to cope with this emergency Nevertheless the greatest skill may not suffice, for obstruction of this sort is often a late complication, and the patient may arrive with the bowel already perforated, moreover many of these patients have what SAMUEL JOHNSON termed the most incurable of all diseases—old age Obstruction does not usually come without warning, diarrhœa, with mucus in the stools, and colicky pain drive most patients into seeking advice Occasionally, however, as Mr RODNEY SMITH pointed out, the doctor may be deceived by the complaint of right-sided abdominal pain, due to cæcal distension or mobility of a distended sigmoid loop[3] In 90% of cases the obstruction—usually of the "napkin ring" type—is in the left colon, and involvement of the right colon nearly always indicates an advanced growth There must be no rushing the patient to the operating-theatre, *ohne Hast, ohne Rast, immer langsam voran* is a good dictum Plain ("scout") radiographs of the abdomen, with the patient supine and erect, should invariably be taken These will demonstrate the cæcum, which serves as the wind sock—the guide to the surgical line of approach—and also clinches the diagnosis of large bowel obstruction The volvulus will be clearly outlined, and the small intestine obstruction will be evident in the parallel loops and multiple fluid pools Moreover, as Mr RODNEY SMITH emphasised, in many cases the ileocæcal valve holds, forming a closed obstruction loop which only operation can relieve, when this valve is incompetent, ballooning of the small intestine is evident on the radiograph The surgeon may then be tempted to introduce a Miller-Abbott tube, but every speaker agreed that this may lose valuable time, for the tube cannot decompress the large bowel, and its passage through the pylorus is unpredictable Passage of a Ryle tube is always necessary, and the anæsthetist must take precautions against regurgitation Fluid replacement is called for, as Mr H E LOCKHART-MUMMERY remarked, but this therapy has to be tempered with fine judgment, particularly in the old Awareness of the hazards of intravenous therapy is now more acute (It has been well declared that more people have been drowned on the banks of the Thames than in it) The saline content of the urine is a sensitive indicator of salt need, and should become a standard ward test Mr E W GRAHAME recommended that if the chloride test is positive, 0 45% saline should be infused, and this should be followed with plasma or even blood

As to the surgical procedure, opinion differed little Cæcostomy, blind or otherwise, was regarded as less satisfactory than transverse colon loop colostomy, preferably through a transverse abdominal incision This affords more effective rapid decompression, and the more complete "defunctioning" is a great advantage in the subsequent stage of resection Some wag, talking of visceroptosis, has suggested that "where a man wears his guts is his own business", but in large-bowel obstruction it is very much the surgeon's concern Fat patients very often have short mesenteries, and, as Mr H R THOMPSON said, the obstructed colon, tethered by its mesentery, expands between the leaves, shortening it even more Delivery of such a colostomy to the surface may thus be difficult or impossible, and the surgeon is sometimes forced to do a cæcostomy This may be difficult If spilling is to be avoided, the bowel should be punctured with a fine needle and then cleared with trochar puncture suction, after suitable packing and purse string suture, satisfactory decompression will be achieved only with drainage through a large tube and exteriorisation of the bowel Cæcostomy may also be advisable for growths of the splenic flexure, for in the subsequent resection the surgeon is not handicapped by an otherwise fixed transverse colon Even the obstructing transverse colon growth is probably better handled in this way than by immediate resection on an area of œdematous mesentery Pelvic colon colostomy is to be avoided, it embarrasses the surgeon in any subsequent resection

Should the abdomen be gently explored at the same time? Obviously the surgeon will be guided by the amount of bowel distension Professor MORLEY suggested that with the anæsthetist's use of muscle relaxants (spinal anæsthetics are hazardous) this was now often possible, and it provided the surgeon with reasonable information for planning further procedures Mr RODNEY SMITH, however, felt that this procedure was dangerous, and from the patient's angle often merely morbid curiosity Mr LOCKHART MUMMERY, who described a study of some 90 case-records collected from five different hospitals, gave examples showing that what seemed an inoperable growth on palpation by this method was often merely due to secondary inflammatory changes Even with secondary growths in the liver, most surgeons now endeavour to remove subsequently the primary growth, and these patients often live for three years in relative comfort[4] Immediate resection and anastomosis, as any surgical tyro knows, has no place in this type of surgery The Paul-Mikulicz procedure though it has a deservedly good reputation in mild subacute obstruction, should not be undertaken here, for it does not safely afford the necessary wide mobilisation of the bowel Obstruction of the right colon, it was also generally agreed, is preferably dealt with by lateral ileocolic anastomosis rather than ileostomy, which might lead to skin excoriation and a distressing convalescence Such anastomosis needs very fine close stitching if leakage is to be avoided, the anastomosis should be placed some twelve inches from the ileocæcal valve and joined to the mid transverse colon Primary hemicolectomy is occasionally permissible, Professor MORLEY recommends in addition E G MUIR's manœuvre of passing a drainage tube through the colon end and via the stoma into the ileum

In the immediate aftercare the electrolyte balance will need attention. House-surgeons to whom drips are delegated should be warned, for otherwise they will not tiptoe as the experienced surgeon does, appreciating more fully the complex physiological issues Increased significance is now attached to the potassium ion[5], and Mr GRAHAME pointed out that the potassium values were high in these cases, probably owing to circulatory failure and associated renal insufficiency The effects of parenteral potassium on the myocardium may be serious, so at least three conditions must be met there must be a daily urinary output of over 750 ml, and each day an electrocardiogram must be taken and the serum potassium level recorded[6] Three weeks seems to be ample time for resolution of the colon œdema and ulceration, and for the wall blood supply to become fit for resection of the bowel End-to end anastomosis is to be preferred, though there is room for personal choice The so called aseptic anastomosis, as Professor MORLEY emphasised, is of no particular advantage at this stage The method of closing colostomies needs further thought by the surgeon This may be a difficult procedure, with occasional deaths The present practice of enterotome crushing of the spur in the Paul-Mikulicz procedure is surely an anachronism Closure of large numbers of colostomies in the belly wounds of war has convinced many surgeons that excision of the

Treatment of Depression

IF, among the many who attended the discussion on depression at the Royal Society of Medicine on March 13, there was anyone who came to see the psychological and somatological schools of psychiatry in open combat, he must have been disappointed Since 1936 Dr CLIFFORD SCOTT, the representative of psycho analysis, has treated selected patients with affective psychoses by the methods of Freudian analysis, but in such cases he still regards this treatment as experimental and full of difficulties and dangers Moreover, during analysis he has observed faints, drowsiness, amnesia, attacks of rage and furor, and sudden suicidal urges—in short, symptoms reminiscent of epilepsy, pointing, he thinks, to an instinctive yearning by the patient for " shock " and convulsive treatment He also found that previous convulsive treatment was helpful to the progress of analytical procedure The number of beneficial results he could quote from psycho analysis alone, was not impressive, but his critical and persistent endeavour to unravel the psychopathology of melancholia in the footsteps of ABRAHAM command respect

Dr SCOTT was preceded by Dr W MAYER GROSS, who began by pointing out the change in therapeutic approach to the affective psychoses within the last fifteen years, through the introduction of convulsive therapy He thought it necessary, however, to recapitulate long established measures Some of these, such as the avoidance of suicidal risks, have in a modified form become more important with the new treatment, others, such as the combating of anorexia, loss of weight, and constipation—formerly the most hazardous tasks in treating depression—hardly present any problem nowadays Depressive illness is still often mistaken for physical disease, and the patient may be treated for gastro intestinal complaints, anæmia, pulmonary tuberculosis, or malignant disease But even if the patient s bodily health is greatly impaired during lengthy investigations before he sees a psychiatrist, once the diagnosis is made a few convulsions will restore all bodily functions, including sleep, before the psychological effect becomes very obvious Wisely used, electrically induced convulsion treatment can transform the outlook of a depressive attack, and the most common mistake, according to Dr MAYER GROSS, is its excessive and indiscriminate use Of all the affective syndromes, involutional depression derives most benefit from convulsion treatment A series of 100 depressive patients over the age of forty, without earlier history of depression, were followed up for two to nine years after being treated at Crichton Royal between 1940 and 1947 At the time of the follow up, 72 were fully recovered, 6 socially recovered, and 11 home invalids, only 3 had had to remain in hospital all the time There had been 8 deaths, 2 by suicide In an equal group of younger manic depressive patients with definite recurrent attacks, the response to convulsive therapy was not so definite, but, despite a larger proportion of relapses, a shortening of suffering and of hospital care was usually apparent The rhythm of the illness and the number of attacks was, however, not influenced by the convulsive treatment

In the general discussion great interest was shown in the type of case that totally or partially resists convulsion therapy Most speakers agreed on its failure in younger patients in whom severe anxiety is associated with depression Opinion was divided on its suitability in reactive depression—i.e, in patients with an acute or chronic conflict situation probably responsible for the depressive illness Dr G GARMANY, the third opener, who dealt mainly with the important use of electric convulsions in outpatient clinics, illustrated his points with some statistics from Westminster Hospital He found the treatment worth while and efficient in reactive depressions, provided the premorbid personality was stable and not of a psychopathic type Little was said about leucotomy in depressive states except for some cautionary counsel that it may destroy the delicate emotional responses which are the great asset of the cyclothymic patient Only for those cases of manic depression in which psychotic attacks follow one another so quickly that the patient has to stay permanently in hospital, is operative treatment indicated, and less damaging and more exactly localised neurosurgical techniques should be sought for such cases

Carcinomatous Obstruction of the Colon

MEDICINE is advancing so swiftly at so many points that any slower progress seems disappointing The mortality from acute obstruction of the colon due to malignant disease is a good example of this slower tempo In the '30s the operative mortality was about 30%, and since then, despite antibiotics, intestinal antiseptics, and other innovations, it has fallen only to some 18–20% By contrast, the mortality of operations on uncomplicated carcinoma of the colon has fallen strikingly The figures of ALLEN et al.[1] indicate a fall from 17 5% to under 2%, and indeed it is reasonably contended that ' barring accidents the surgeon may be reasonably confident that his patient will survive such uncomplicated colon resection[2]

At the Royal Society of Medicine on March 7, Prof JOHN MORLEY, opening a discussion on large bowel obstruction due to malignant disease, urged the need for clear instructions to registrars, who are most commonly required to cope with this emergency Nevertheless the greatest skill may not suffice, for obstruction of this sort is often a late complication, and the patient may arrive with the bowel already perforated, moreover many of these patients have what SAMUEL JOHNSON termed the most incurable of all diseases—old age Obstruction does not usually come without warning, diarrhœa, with mucus in the stools, and colicky pain drive most patients into seeking advice Occasionally, however, as Mr RODNEY SMITH pointed out, the doctor may be deceived by the complaint of right sided abdominal pain, due to cæcal distension or mobility of a distended sigmoid loop[3] In 90% of cases the obstruction—usually of the ' napkin ring " type—is in the left colon, and involvement of the right colon nearly always indicates an advanced growth There must be

no rushing the patient to the operating-theatre, *ohne Hast, ohne Rast, immer langsam voran* is a good dictum. Plain ("scout") radiographs of the abdomen, with the patient supine and erect, should invariably be taken. These will demonstrate the cæcum, which serves as the wind-sock—the guide to the surgical line of approach—and also clinches the diagnosis of large bowel obstruction. The volvulus will be clearly outlined, and the small intestine obstruction will be evident in the parallel loops and multiple fluid pools. Moreover, as Mr RODNEY SMITH emphasised, in many cases the ileocæcal valve holds, forming a closed obstruction loop which only operation can relieve; when this valve is incompetent, ballooning of the small intestine is evident on the radiograph. The surgeon may then be tempted to introduce a Miller Abbott tube, but every speaker agreed that this may lose valuable time, for the tube cannot decompress the large bowel, and its passage through the pylorus is unpredictable. Passage of a Ryle tube is always necessary, and the anæsthetist must take precautions against regurgitation. Fluid replacement is called for, as Mr H E LOCKHART-MUMMERY remarked, but this therapy has to be tempered with fine judgment, particularly in the old. Awareness of the hazards of intravenous therapy is now more acute. (It has been well declared that more people have been drowned on the banks of the Thames than in it.) The saline content of the urine is a sensitive indicator of salt need, and should become a standard ward-test. Mr E W GRAHAME recommended that if the chloride test is positive, 0·45% saline should be infused, and this should be followed with plasma or even blood.

As to the surgical procedure, opinion differed little. Cæcostomy, blind or otherwise, was regarded as less satisfactory than transverse colon loop colostomy, preferably through a transverse abdominal incision. This affords more effective rapid decompression, and the more complete "defunctioning" is a great advantage in the subsequent stage of resection. Some wag, talking of visceroptosis, has suggested that "where a man wears his guts is his own business", but in large bowel obstruction it is very much the surgeon's concern. Fat patients very often have short mesenteries, and, as Mr H R THOMPSON said, the obstructed colon, tethered by its mesentery, expands between the leaves, shortening it even more. Delivery of such a colostomy to the surface may thus be difficult or impossible, and the surgeon is sometimes forced to do a cæcostomy. This may be difficult. If spilling is to be avoided, the bowel should be punctured with a fine needle and then cleared with trochar puncture suction, after suitable packing and purse string suture; satisfactory decompression will be achieved only with drainage through a large tube and exteriorisation of the bowel. Cæcostomy may also be advisable for growths of the splenic flexure, for in the subsequent resection the surgeon is not handicapped by an otherwise fixed transverse colon. Even the obstructing transverse colon growth is probably better handled in this way than by immediate resection on an area of œdematous mesentery. Pelvic colon colostomy is to be avoided; it embarrasses the surgeon in any subsequent resection.

Should the abdomen be gently explored at the same time? Obviously the surgeon will be guided by the amount of bowel distension. Professor MORLEY suggested that with the anæsthetist's use of muscle relaxants (spinal anæsthetics are hazardous) this was now often possible, and it provided the surgeon with reasonable information for planning further procedures. Mr RODNEY SMITH, however, felt that this procedure was dangerous, and from the patient's angle often merely morbid curiosity. Mr LOCKHART-MUMMERY, who described a study of some 90 case records collected from five different hospitals, gave examples showing that what seemed an inoperable growth on palpation by this method was often merely due to secondary inflammatory changes. Even with secondary growths in the liver, most surgeons now endeavour to remove subsequently the primary growth, and these patients often live for three years in relative comfort.[4] Immediate resection and anastomosis, as any surgical tyro knows, has no place in this type of surgery. The Paul-Mikulicz procedure though it has a deservedly good reputation in mild subacute obstruction, should not be undertaken here, for it does not safely afford the necessary wide mobilisation of the bowel. Obstruction of the right colon, it was also generally agreed, is preferably dealt with by lateral ileocolic anastomosis rather than ileostomy, which might lead to skin excoriation and a distressing convalescence. Such anastomosis needs very fine close stitching if leakage is to be avoided; the anastomosis should be placed some twelve inches from the ileocæcal valve and joined to the mid transverse colon. Primary hemicolectomy is occasionally permissible; Professor MORLEY recommends in addition E G MUIR's manœuvre of passing a drainage tube through the colon end and via the stoma into the ileum.

In the immediate aftercare the electrolyte balance will need attention. House-surgeons to whom drips are delegated should be warned, for otherwise they will not tiptoe as the experienced surgeon does, appreciating more fully the complex physiological issues. Increased significance is now attached to the potassium ion,[5] and Mr GRAHAME pointed out that the potassium values were high in these cases, probably owing to circulatory failure and associated renal insufficiency. The effects of parenteral potassium on the myocardium may be serious, so at least three conditions must be met: there must be a daily urinary output of over 750 ml, and each day an electrocardiogram must be taken and the serum potassium level recorded.[6] Three weeks seems to be ample time for resolution of the colon œdema and ulceration, and for the wall blood-supply to become fit for resection of the bowel. End to end anastomosis is to be preferred, though there is room for personal choice. The so called aseptic anastomosis, as Professor MORLEY emphasised, is of no particular advantage at this stage. The method of closing colostomies needs further thought by the surgeon. This may be a difficult procedure, with occasional deaths. The present practice of enterotome crushing of the spur in the Paul Mikulicz procedure is surely an anachronism. Closure of large numbers of colostomies in the belly wounds of war has convinced many surgeons that excision of the

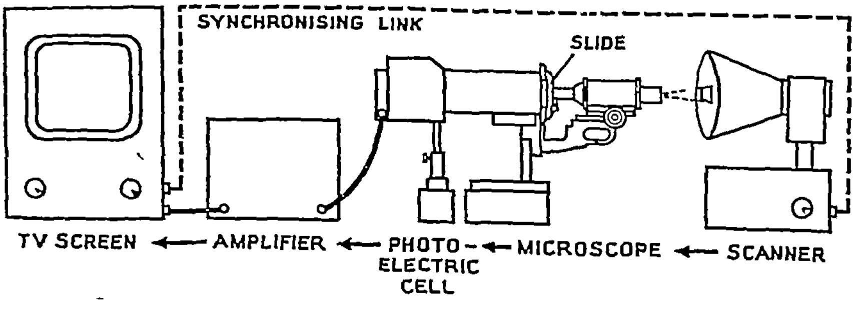
THE FLYING-SPOT MICROSCOPE

AT a recent meeting of the Society of Experimental Biology, Prof J Z Young, F R S, and Mr F Roberts[1] demonstrated a new method of producing, by combination of optical and electronic techniques, a magnified image of a microscopic object The method consists in scanning an object by focusing on it the image of the flying-spot of a cathode ray tube, and allowing the light transmitted to fall on a multiplier photocell, the output of which is used to modulate the luminosity of a televising tube The luminous spot of the cathode ray tube moves along a system of closely spaced parallel lines to form an even luminous area, known as the scanning rastor Thus all elements of the object are illuminated during scanning The cathode ray and the televising tubes are locked together, that is to say, the motion of the flying spot of one tube is synchronised with that of the other It follows that, if the elements of structure absorb or scatter light, the intensity of the flying spot of the televising tube will be modified as each element is illuminated, and a picture which represents the object will be developed on the screen

Twenty years ago Synge[2] suggested increasing resolution by passing the object over an illuminated aperture whose dimensions are very small compared with the wave length of light, and building up a magnified image with photoelectric apparatus as in telephotography Because of technical difficulties he abandoned this idea but suggested that a spot of light might be projected into the moving object by a microscope-objective He concluded, however, that no increase of resolution would be gained by this method In the flying spot microscope a microscope objective is used as a condenser The rastor of the cathode ray tube is situated in the primary image plane of the lens—i e, approximately in the position occupied by the eye lens of the ocular when the objective is used in the normal way The light transmitted by the object may be concentrated on the photocell by a collector lens, but this does not seem to be of importance, for the high sensitivity of the photocell allows illumination of low intensity to be used

An important feature of the method is the ease with which the contrasts may be increased or decreased according to whether the object is of low or high opacity These changes are strikingly demonstrated when transparent objects, such as diatoms, are examined Magnification can be continuously varied by merely increasing or decreasing the area of the scanning rastor The brightness of the background, which is easily controlled, is not affected by changes in magnification For teaching and demonstration purposes a cathode ray tube of the projection type is substituted for the televising tube, and a bright image covering an area 3 ft square can be projected on a lantern screen The image of the spot of light scanning the object will, in general, be similar to that of a point source and will consist of a diffuse disc of light surrounded by diffraction rings This distribution is not present in the spot which builds up the image on the viewing screen, and on theoretical grounds it seems that resolution may be increased beyond the limits of ordinary microscopical methods

As the method is developed, its applications may be extended to include scanning by ultraviolet and infra red radiations and accurate determination of the absorption of structures in living and stained materials At the moment interest is chiefly confined to developing a technique for counting and measuring the sizes of cells and other microscopic objects, and the method may prove of unique value for counting blood-cells



COMPARATIVE ALLERGY

ANAPHYLAXIS as induced in laboratory animals bears little resemblance to allergic disorders as seen in man There is increasing evidence, however, that domestic animals suffer from a variety of allergic diseases comparable with those of human beings. Dr W R Thrower, speaking at a joint meeting of the National Veterinary Medical Association and the British Association of Allergists in London a few weeks ago, classified the allergic reactions common to man and animals into those in which the symptoms and signs are mainly respiratory, and those in which they are mainly cutaneous The latter group includes not only eczema, urticaria, and angioneurotic œdema, but also unclassified but still mainly ectodermal responses such as laminitis in horses

Thrower pointed out that, though allergic disorders are endemic in every human community, they are much commoner among immigrants who become exposed to sensitising agents not previously encountered This explains, he says, why they are more prevalent in young countries like Australia and the United States than in Great Britain Among animals the same holds true, and dogs and cattle imported into the United States show a higher incidence of allergic diseases than in their native land Before diagnosing such diseases in animals one must be careful to exclude extraneous factors such as infection thus in dogs, identification of the true basic condition is usually difficult, because parasitic mange and secondary coccal infection are often superimposed Nevertheless, after making allowances for this, American dogs seem to be abnormally allergic Allergic reactions in dogs do not depend solely on a true antibody reaction because endocrine imbalance may be a contributory factor, a striking example is the acute angioneurotic œdema seen in recently whelped bitches Horses are especially liable to allergic disorders, of which urticaria and laminitis are the commonest But acute urticaria may not always be truly allergic for horses are very sensitive to nettle stings, which can excite a generalised reaction

The use of the anti histamine compounds in treating certain superficial allergic conditions in animals shows them to be as effective as they are in similar conditions in man, and it is important to note that in both man and animals it is the allergic reactions of epiblastic structures which can be successfully treated by their use It was the successful clinical trial of the effect of anti histamine drugs in laminitis which revealed the allergic nature of this serious cause of lameness

In man a tendency to allergic responses is often inherited, and comparative studies of the genetic factor in animals are needed Among cattle there are many specific antigenic reactions which are directly transmissible, but it is doubtful whether the common cutaneous allergies of cattle are passed to the offspring The most striking example of cutaneous allergy is bloat, which is almost certainly due to sensitisation to the proteins of *Hypoderma bovis* acute attacks can be induced by careless manual extrusion of the

wound scar, a fresh end to end anastomosis, and replacement of the bowel within the peritoneal cavity is now a safe undertaking, especially with intestinal antiseptics Spur crushing entails a wait of six weeks to two months before the surrounding tissue is soft enough to turn in snugly and safely In such circumstances PAUCHET's manœuvre of slitting each bowel loop and then fashioning an anastomosis yields a first-class closure[7]

The ultimate prognosis is relatively poor In a small series of cases NICKELL and DOCKERTY[8] found the chance of five year survival half that for the non-obstructing lesion, and they suggested that the massaging effect of the vigorous peristalsis and the inflammatory œdema would encourage cancer-cell spread There can be no better adornment to the house surgeon's room than a plaque with the words " Never let the sun set or the sun rise on an intestinal obstruction "

Annotations

BREAKDOWN IN STUDENTS

THE examination syllabus, the discovery that a brain well respected at school may after all be second rate, and the concurrent flowering of the sexual instinct, combine to press hardly on undergraduates, and they seldom confide their difficulties to anyone but a friend in like case This state of stress is reflected in the figures given on another page by Dr Parnell for mortality and prolonged illness among Oxford undergraduates, and in the American studies he quotes In his series, mental illness and nervous breakdown accounted for more than half the illness lasting more than a term, and the suicide rate was significantly higher than that of the civilian population of the same age Tuberculosis accounted for nearly another quarter of the total illness, though only one undergraduate died of tuberculosis during the investigation As Dr Parnell points out, the relative importance of mental disorder and tuberculosis among students has not so far been generally recognised, and the fact that two thirds of those who lost a full term's residence because of mental illness and nervous breakdown later returned to continue their university course does not make things much better He notes the need for more detailed study of the mental health of students and of the means for preventing mental illness among them As an interim measure, we should surely admit to these young people that this is a period of special stress If at the start of their course they were clearly warned by their schoolmasters or tutors that they are entering an experience which many find troubling, and if some experienced person—whether doctor, psychiatrist, or college authority—could be mentioned as a recognised adviser to those in difficulties, undergraduates, even if they ignored the proffered help, would not feel that overwhelming shame at failure to reach an intended mark which contributes to many breakdowns

REABLEMENT FOR MENTAL PATIENTS

THE moment of discharge from a mental hospital is inevitably disturbing for the patient Not only must he change a sheltered and encouraging environment for one of competition and indifference, but he must perforce do it without much confidence in his own powers of resistance to strain Moreover, he is going to encounter some conscious and unconscious cruelty from the less imaginative of his associates all of which he foresees, or suspects may come That he needs some help in adjusting himself to such stresses goes without saying, and there are several ways of providing it It comes best and most naturally, perhaps, through a quiet and secure home life, but relationships in the home have often contributed to his breakdown, and what should be a place of safety becomes, or remains, a danger point During the war the National Association for Mental Health gave such people great help through their community care scheme, under which a psychiatric social worker would make personal friends with them, and stand by them with advice, sympathy, and practical help, until they were again able to face their full responsibilities Unfortunately this scheme had to be largely given up under the National Health Service, since the duty for such after care was laid on the local authorities Some of these are making good use of the experience gained from the N A M H scheme, but few have organised any comparable service as yet

Another way of helping the patient is to give him the chance to attend a social club Many mental hospitals nowadays arrange such clubs for their discharged patients, and find them very successful, and the Institute of Social Psychiatry has long run therapeutic social clubs, not only for discharged patients, but for others who are mentally disturbed, neurotic, psychopathic, or delinquent, as well as some who are merely unstable, or abnormally reserved and solitary The parents of maladjusted children, too, may benefit by joining such clubs, and the children enjoy a secondary gain in security A new After Care Rehabilitation Centre, recently set up by the institute, was officially opened by Mr Hilary Marquand, the Minister of Health, on March 14, at Christchurch House, Chancel Street, London, S E 1 Patients attend daily for occupational therapy, group discussions, and cultural activities, all of which help them to express themselves, to get to know each other, and to take a growing amount of responsibility Those who need psychological help can have it from the Social Psychotherapy Centre run by the institute. In his opening address the Minister spoke of the part the institute can take in the reablement of ex Servicemen suffering from neuroses or psychoneuroses, and wished the work well The institute is anxious to forward research in this field, but, as Dr Noel Harris, chairman of the board of governors, pointed out, this needs funds

A RURAL PERIL

IN his Ernestine Henry lecture at the Royal College of Physicians eighteen months ago, Dr Donald Hunter[1] drew attention to the very serious accidents possible through careless use of the toxic substances now employed in agriculture as weedkillers and insecticides —notably the organic phosphorus insecticides In the United States all too much information has already been collected about the signs and symptoms of poisoning among those who have used toxic sprays without taking proper precautions, and among those who have been otherwise exposed to the poisons Since the report of a working party set up by the Ministry of Agriculture with Prof S Zuckerman, M D, F R S, as chairman, the National Farmers' Union has issued warnings to farmers,[2] and the Ministry has conferred with the British Medical Association on the medical side To remind doctors of the risk, the symptoms, and the recommended treatment, of this kind of industrial poisoning, the B M.A last week sent a circular to general practitioners, consultants, and medical officers of health When spraying is to take place, the Ministry of Agriculture will inform the county or county borough M O H, who will pass on the information, through the B M.A divisional secretaries, to all doctors in the area

MORTALITY AND PROLONGED ILLNESS AMONG OXFORD UNDERGRADUATES

R. W. PARNELL
D.M. Oxfd, M.R.C.P.
PHYSICIAN IN CHARGE OF STUDENT HEALTH SERVICE, INSTITUTE OF SOCIAL MEDICINE, OXFORD

VERY little has been published in this country on mortality and morbidity among students. The present survey is the first to present figures from Oxford University, and has been made possible by the friendly cooperation of the college authorities. Twenty six colleges and halls have supplied information about undergraduates' mortality and prolonged illness (i.e., illness causing the loss of at least one full term's residence) between Jan. 1, 1947, and Dec. 31, 1949. Wherever possible the nature of the illness was stated and the end result recorded in the form "returned to college," "went down," or "still in doubt." The data may be incomplete because time and labour did not suffice for an exhaustive study of college records, and because such records are commonly kept for financial purposes, not for recording sickness. Nevertheless, the figures contribute to our knowledge of the relative incidence, and to some extent of the actual prevalence, of prolonged absence on account of sickness.

The total population annually at risk during the period under review was 6142 (5048 men and 1094 women).* This figure was arrived at by determining the average number of undergraduates in residence during the four academic years 1946–49 and subtracting the appropriate number for two colleges from which no return was received.

TABLE I—PRINCIPAL CAUSES OF DEATH IN YOUNG MALE ADULTS

Oxford University 1947–49 compared with England and Wales 1947

Causes	England and Wales Ages 15–24			Oxford University		
	No	Annual rate per 100 000 living	% all causes	No in 3 yr	Annual rate per 100,000 living	% all causes
All causes	3986	183·4	—	33	217·9	—
Tuberculosis (respiratory 994) (other forms 209)	1203	55·4	30·2	1	6·6	3·0
Violence (road accident 419) (other violence 520)	939	43·2	23·6	16	105·7	48·5
Heart-disease	251	11·5	6·3	—	—	—
Respiratory (pneumonia 121) (bronchitis 51) (other 48)	220	10·1	5·5	—	—	—
Alimentary (appendicitis 83) (ulcer of stomach or duodenum 23) (other digestive 75)	181	8·3	4·5	2	13·2	6·1
Cancer	156	7·2	3·9	—	—	—
Nephritis	126	5·8	3·2	—	—	—
Suicide	114	5·2	2·9	9	59·4	27·3
Acute poliomyelitis and encephalitis	84	3·9	2·1	2	13·2	6·1

Total male civilian population ages 15–24—2,173,000

MORTALITY

There were 35 deaths (33 men, 2 women). 17 (16 men 1 woman) were accidental—6 on the roads, 4 in mountaineering, and 3 by drowning. Suicide accounted for 9 deaths (all men); poliomyelitis for 2 (men); tuberculosis for 1 (man); and other causes for 6 (1 woman).

The annual death rate of men undergraduates at Oxford in the period 1947–49 was 218 per 100,000 living. This is 119% of that of the age group 15–24 in England and Wales in 1947 (table I). Tuberculosis, which caused 30% of all civilian deaths in this age group in 1947 killed only 1 Oxford undergraduate in 1947–49 and heart-disease, mainly rheumatic, which caused 6·3% of all deaths in this age group did not cause any undergraduate death at Oxford. In fact, these two causes of death, which are known to be more common at lower socio-economic levels, were almost absent among undergraduates. On the other hand, risks which are more prevalent in the upper social classes figured prominently in this series. For example, accidents were responsible for 48% of undergraduate deaths as compared with 24% of all deaths among civilians of the same age in England and Wales. The suicide rate among undergraduates (59 per 100,000 living) was 11 times that of the 15–24 civilian age group as a whole (5·3 per 100,000 living) and 17 times that of the same age group in the Armed Forces (3·5 per 100,000 living). Further, whereas suicide caused only 2·9% of all deaths in young male adults in this country (1947), it caused 27% of male undergraduate deaths at Oxford (1947–49). However caution must be observed in interpreting these figures, because the total university suicides numbered only 9 in three years.

TABLE II—STANDARDISED MORTALITY RATIOS BY REGISTRAR GENERAL'S SOCIAL CLASSES AT AGES 15–24

Cause of death related to social class	Social class		
	I and II	III	IV and V
A *Uninfluenced*			
All causes	95	92	79
Tuberculosis (other than pulmonary)	87	86	94
Nephritis	96	91	99
B *Higher in IV and V*			
Pulmonary tuberculosis	72	97	101
Pneumonia	69	88	110
Ear and mastoid	—	88	122
Rheumatic fever	—	90	102
Heart disease	75	87	99
Valvular disease	77	83	100
C *Higher in I and II*			
Accidents	131	103	95
Appendicitis	108	105	91
Suicide	174	87	107

Greenwood et al. (1941) showed how the suicide rate in England and Wales has risen during this century, and they pointed out that as long ago as 1880 the Registrar General said that suicide was commoner among the educated than the uneducated. The question arises whether suicide is a special hazard of student life, or is merely more common in the social classes to which undergraduates belong. This question is easily answered. The standardised mortality ratio (S.M.R.) of suicide in social classes I and II (from which 78% of undergraduates are drawn) was 174 in 1930–32, 100 is taken as the S.M.R. for all social classes (table II). Among students, however, the suicide rate is far higher even than that of classes I and II.

It might be argued on the evidence presented so far that the high suicide rate is a post war phenomenon which is unlikely to continue in peace time. It is known from inquest reports that 4 at least of the 9 suicides occurred in ex Servicemen, and the difficulty of their readjustment warble larvæ Another bovine disease very similar to the condition seen in man is the so called spring catarrh, seen at its maximum during the pollen season, when human beings are suffering from hay fever Its diagnosis has various pitfalls because a cow may cough for many different reasons, the commonest being the mechanical irritation of dust derived from concentrates in the cow house or grass pollen in the field Skin sensitivity tests reveal that certain allergic reactions may be due to the common pollens, or often to various moulds found on grasses, and particularly in musty hay The term food allergy is often used without a real understanding of its meaning, for sometimes it is not the food itself that is at fault but some contaminant, which is often found to be a mould

---

* These figures are substantially less than the totals recorded in the University Calendar for undergraduates on the books. The latter figure is 9718 (men 8437 women 1281) but the number in residence is believed to be more correct for the purpose of the survey.

ADMINISTRATIVE FAILURE

As a people who are attempting to follow on a national scale that difficult injunction about loving our neighbours, we have at the moment some cause for self respect At first sight, the difference between private charity and public responsibility is that one depends on people and the other on regulations, and it is easy to say that regulations are less human and flexible than people, and that you cannot hope to do by rule what good men have always done from kindness But good men have always been fewer than the occasions on which they were needed less than a century ago (before the idea of mutual responsibility had taken such a hold on our sense of justice) people were more often left in need than succoured, and the need was often dire Legislation has so changed things that nowadays we hear not of misfortunes successfully relieved but of the individual case where someone was denied an undoubted necessity That we are more disturbed by one such case than our forerunners would have been by twenty of the kind proves that we have at least some confidence in regulations having made them we expect them to work, and we are rightly indignant when the machine breaks down

Two days before Christmas, an elderly man was found dying outside the hut in which he had been living, on Urmston Meadows, Manchester The evening before, he had been refused admission to a general hospital (because he was not thought to be ill enough to need a bed) and to a welfare hostel (because he was too ill to be accepted) Between two sets of regulations, it may be said, the poor man was denied a bed to die in—a result which certainly suggests some failure in human flexibility According to the *Manchester Guardian*,[1] the West Manchester Hospital Management Committee, after an inquiry, exonerated the doctors responsible, but at once made temporary arrangements to set aside beds for those who need care rather than urgent medical treatment, until a “ realistic liaison ” can be established between the hospital service and the local authority service responsible for looking after such cases On the other hand, the Minister of Health,[2] answering Mr Samuel Storey's question on March 15, described the failure as due to an error of judgment in not admitting this man to hospital and not to any lack of liaison between the health and welfare services, he said that such patients will in future be admitted to hospital, and that they will not be sent on to another hospital until it has been ascertained that there is a bed for them This is surely a moral duty which every hospital in the country should now accept

The story makes vividly clear the need for hostels, of the type now being set up by the National Association for Old People's Welfare and King Edward's Hospital Fund [3] to work with the hospitals, receiving from them old people who are well enough for discharge but not well enough to go back to their former homes, and sending into them infirm old people who fall sick while they are resident in the hostel The need for such a two way service has become increasingly clear since the Act did away with both the relieving officer, and the statutory duty to admit which formerly rested on public assistance institutions Nowadays the busy hospital resident has no hospital to which he can count on sending the unwanted—or unsuitable—patient, and his own judgment of the patient's need, as this case reminds us, can never be infallible He has, however, three other sources of help to which he can turn the general practitioner, the medical officer of health, and the voluntary associations The M O H can at least send to the patient's bedside a district nurse and a home help, the voluntary bodies will provide such things as bedding and blankets The family doctor may have sent the patient in, and will be ready enough to discuss the home conditions and the possibilities of adapting them to the sick man's needs All these helpers are at the end of a telephone wire in the day time (though as a rule only the family doctor will be available at night), but it is not certain that they are always used as fully as they might be Collaboration in the health service is still intermittent, local, and variable Regulations in the last resort must always be put into effect by people, and there will always be some people who will attend to the letter of a regulation rather than the spirit For this reason responsible bodies in every part of the country should take thought to ensure that regulations are properly backed by facilities

WORLD HEALTH DAY

To the peoples of its member countries the United Nations Organisation has proved a disappointment This is understandable, because they hear most about the proceedings of the General Assembly and the Security Council where amicable agreement on world problems has been rare, and misunderstanding, argument, and the veto depressingly common It is unfortunate, therefore, that they know so little about those special agencies of UNO which have achieved so much Of these the World Health Organisation is one of the most successful, for it has used its relatively small resources to good effect, and it particularly needs to be better known because it works chiefly by helping people to help themselves Before they will do this, they must be told of the health problems of their own and other countries, and of the ways in which they can help to solve the problems Accordingly, W H O suggests that April 7 of each year should be observed as World Health Day, and asks that on this day all the resources of modern publicity be used to tell the public about the work of their own health services and of W H O For this year's World Health Day, W H O has adopted the theme “ Health for your Child and the World's Children,” for it recognises that any long term plan for improving world health must have as its basis the mental and physical needs of the child It is in this sphere that the help of the public is especially needed, and they must be told what has already been done and how much more can be done if they will do it

---

Sir WILLIAM DOUGLAS, permanent secretary of the Ministry of Health since 1945, is to retire on April 30 Sir William has remained at his post till the changes due to the creation of a separate Ministry of Local Government and Planning were completed

Mr J M K HAWTON, C B, at present a deputy secretary at the Ministry of Health, will succeed Sir William, and Mr I F ARMER, now an under-secretary, will take Mr Hawton's place

ON March 19 Dr W RUSSELL BRAIN was re elected president of the Royal College of Physicians of London

[3] *Lancet* March 17 1951 p 625 and March 24 1951 p 696

It affects a student population of about 70 000 at British universities, in addition to the large number at technical and training colleges

SUMMARY

1 Accident caused 17 of 35 undergraduate deaths at Oxford University in the three years 1947–49

2 Suicide accounted for 9 undergraduate deaths (during both term and vacation) A suicide rate calculated from this data gives a significantly higher figure than that for the civilian population of the same age, higher than that for the Registrar-General's social classes I and II, and higher than that in the Armed Forces

3 Tuberculosis caused 1 death only, and rheumatic heart-disease none

4 During the same three years 145 undergraduates lost one full term's residence on account of illness.

5 Mental illness and nervous breakdown accounted for 52 5%, tuberculosis for 23%, and other conditions for 24 5% The relative importance of mental disorder and tuberculosis among students has not received general recognition in the past

6 Two thirds of those who lost a full term's residence because of mental illness and nervous breakdown returned later to continue their university course.

7 In the absence of earlier records there is no evidence of an alteration in mortality rates or in the actual or relative frequency of particular causes of prolonged illness

8 There appears to be ample justification for further and more detailed investigation into the mental health of students and the prevention of mental disorder

I am indebted to various health officers for discussion on this subject and to Dr A. H. T Robb Smith for advice on the method of survey The university kindly supplied figures from which the population at risk was calculated My special thanks are due to colleagues on the staff of the institute, to Mrs C C Standley for checking the analysis of returns to Dr W T Russell and Dr L Sutherland for statistical advice, and to Dr Alice Stewart for various helpful suggestions

EDUCATION ON ALCOHOLISM

FORBES CHESTON *

IN the U S.A. the National Committee for Education on Alcoholism was founded in October, 1944 For the first five years, as the fifth division of the Yale Plan on Alcohol it existed under the sponsorship of the Laboratory of applied physiology of Yale University, but just over a year ago this connection was severed. The committee now known as the National Committee on Alcoholism, has reached the maturity of independence as a public health organisation

The committee was formed because of general ignorance about alcoholism As Mr Yvelin Gardner, acting executive director of the committee remarked in his report for 1949 [1]

> "The mantle of stigma covered the subject. Constructive action on the part of individuals alcoholics or others, was still spotty and isolated largely because of lack of knowledge of where to go or what to do and the shame attendant on everything concerning alcoholism. The therapeutic professions were almost entirely unconcerned with the problem. Governmental activity was limited to punishment in jails and in a few hospitals, to temporary drying out techniques not related to any treatment of the condition"

It was felt that unless people learned at least some of the facts, nothing at all would be done The original aim was to disseminate the findings of the other divisions of the Yale Plan, presenting these in a form understandable by everyone, and now the committee seeks by education to mobilise public opinion for action on the problem The committee's educational work rests on three concepts (1) that alcoholism is a disease and the alcoholic a sick person, (2) that the alcoholic can be helped and is worth helping, and (3) that this is a public-health problem and therefore a public responsibility

When the N C E.A officially announced the opening of its New York offices, everyone of the nine daily newspapers of New York City carried the story Within a few days the news had spread all over the country and mail began to pour in. Mr Dwight Anderson, executive director of the Medical Society of the State of New York wrote

> "Looking back ten years we realise that the idea that the alcoholic was an utterly hopeless person was practically universal, not only among the public but among the medical profession as well Today the public is ready for educational work on a broad scale such as the National Committee is to take It is the beginning of a new public health movement It is the first step towards getting the alcoholic out of gaol and into hospital towards making it possible for the medical man and the psychiatrist the social worker and the lay therapist to pool their skills in modifying the ravages of an illness to which society has been indifferent almost to this very moment'

In September, 1946, just two years after the founding of the committee, Mrs Marty Mann, its executive director, stated that 14 cities in the U S.A had formed representative citizens' committees, affiliated with the national committee, and that these committees had already launched programmes of community action, and she pointed out that this type of coordinated organisation reduced the problem to a more manageable scale Mrs Mann noted that 'our stated primary aim, that of arousing public interest in the problem of alcoholism, seems well on the way to achievement", and she quoted her own final words in the March of Time film *Problem Drinkers* 'The problem of alcoholism can be solved by a plan of community action The National Committee stands ready to help your community to plan such action"

In the years since 1946 the function of the National Committee has changed from one of stimulation to one of guidance The annual report for 1949 showed the great expansion which had taken place The number of affiliated committees had risen to over 50, and clinical and hospital facilities and information centres had been established in many cities. There were now 22 State-sponsored programmes on alcoholism, developed from the work and guidance of the national committee

Industry, too, is beginning to acknowledge that it has a costly problem on its hands. Several major industries have disclosed programmes undertaken on the premise that alcoholics are sick people who can be rehabilitated The Consolidated Edison Company of New York has revealed that it is now pensioning chronic alcoholics where the employee has long been with the company and medical study indicates a compulsive urge to drink Du Pont de Nemours & Company has announced through its medical director that over one hundred valued employees have been restored to the company through the initiation of a programme which recognised and treated alcoholism as an illness In Wisconsin a proto academic life was stressed at the inquests. Pre-war figures are not available for British universities, but the University of Michigan (1945) published student death-rates from 1913 to 1942, during which period suicide caused about 15% of all deaths, accident 35%, and illness 50%.† At the University of Michigan, where the average annual entry was 11,614, Raphael et al. (1937) found that suicide or the possibility of suicide was deemed an important element in 313 students who had attended the mental hygiene unit of the university health service during the previous five years. At Harvard, where the entry in 1939–40 was 6400, there were 6 deaths, including 2 by suicide in that year. At Yale, where the annual entry was about 5000, Fry and Rostow (1942) reported 8 deaths from suicide in the ten years following 1924. In fact, the importance of suicide was recognised by university health services in the U.S.A. before the second world war.

PROLONGED ILLNESS

The total number of undergraduates who missed at least one full term's residence through illness was 145 (113 men, 32 women). Tuberculosis and mental illness (which are discussed below) were responsible for 23% and 52.5% respectively. In the remaining 24.5% the causes of absence included epilepsy, jaundice, asthma, peptic ulcer, concussion, accident, appendicitis, war wounds, and tropical diseases.

Tuberculosis.—33 undergraduates (28 men, 5 women) lost a term or more on account of tuberculosis during the three years under review. It may be assumed that this absence was caused by serious illness, and was not due to minimal lesions detected by mass radiography; the latter was performed at only three colleges and their 6 cases each required at least three months' bed rest, or hospital or sanatorium treatment.

Mental illness and nervous breakdown.—Of the 76 absent for not less than a term, 49 (64.5%) returned to college; 16 (21%) went down without a degree not to return; and 11 (14.5%) went down but their future is undecided. 9 (12%) were stated to have been in a mental hospital or to have been diagnosed as schizophrenia. Of these 3 returned to college, and 2 others were said to have been cured, although they did not return.

The returns show that mental illness, including nervous breakdown, was responsible for just over half the illness, serious enough to cause absence for at least a full term.

However, it has already been stated that, owing to certain factors connected with the method of survey, the morbidity figures probably fall short of the truth. As far as the mental cases are concerned, there are further reasons for this belief. The 9 suicides are not included in the total, nor is there any information about the attempted but unsuccessful suicides which are known to have occurred in the university. Several nervous breakdowns were precipitated by pre-examination stress, and, in the case of any breakdown occurring towards the end of term, and in particular the Trinity Term, at least two months were available for mental rest and recovery without loss of a term's residence. Then, there are other forms of serious mental disturbance involving extreme problems of discipline or behaviour, deep anxieties, obsessions, or ideas of persecution which do not entail absence from college. Fry and Rostow (1942), after ten years' experience at Yale, noted that 16 of their 116 serious cases did not require to leave college at all, and 12 others required only a short period of hospital or other care. In fact, it may be estimated that not less than 0.5% and probably nearer 1% of the undergraduate population in residence each year at Oxford suffers some serious form of mental illness or nervous breakdown.

For many years enlightened college authorities and college doctors have been convinced of the importance of mental hygiene. When, however, the question of preventive action is discussed there is a general feeling that "common sense" is an adequate tool for handling the problem, and no special measures are required. Those interested in the mental welfare of students are thought to be prejudiced, and their personal experience unrepresentative. I found from routine health examinations that psychological disturbances, although mostly of a minor character, were unduly common (Parnell 1947), but the significance of the finding was doubtful. It might have been due to the excessive thoroughness of the examination, or possibly even to the over-sympathetic outlook of the examiner. It was the need for objective confirmation of a clinical impression which first prompted this objective survey, which shows that mental disorder is the principal cause of prolonged illness.

In these circumstances it is natural to ask what preventive steps might be taken, although no scheme is likely to prevent all forms of psychosis.

Preventive measures need not and should not pay too much attention to individuals. They should not involve healthy young men in routine psycho-analysis, nor need they, in a popular but ugly phrase, "stir up the mud" unnecessarily. They need not provoke hypochondria or encourage introspection, nor need they sap self-reliance or engender a feeble and dependent state of mind. Serious opposition to the adoption of preventive measures is founded on the alleged ineffectiveness of individual methods. Close tutorial supervision, with particular attention to the early signs of mental staleness and cumulative fatigue, should help. Better individual instruction in the principles of mental hygiene, in particular in the optimum hours of work, is also required, and it would be desirable to have a doctor or psychiatrist well versed in college life readily accessible for consultation. There is evidence that less severe forms of mental or nervous disorder are more common than the severe forms discussed so far, and the preventive measures suggested apply to them with equal force.

In war, inactivity because of uncertainty about the technique of victory is inexcusable. So too, in the fight against mental ill health preventive measures should not wait indefinitely upon the improbable discovery of some new technical device for early detection. On the other hand whatever action is contemplated in the light of present knowledge, it is clear that further and more detailed study of the problem is urgently needed.

DISCUSSION

The question will certainly be asked whether this paper draws attention to a state of affairs long present but hitherto unrecognised, or whether there has been a recent increase in the prevalence of mental disorder. Since no report has been discovered of any previous survey on these lines, precise evidence on this point is lacking. The gravity of the position may not have been recognised because the undergraduates with tuberculosis, mental illness, and the like have been treated by a number of different departments. In any event, it is clearly desirable that the facts should be widely known.

At a recent conference student health officers expressed concern at the absence of precise information on the incidence of mental ill health among students. To remedy this, and to make comparative study possible between universities, some uniform system of recording serious and prolonged illness is clearly desirable. Preliminary work to establish such a system is now advanced, and it is reasonable to hope that before long it will be ready

---

† Only deaths occurring during the nine months per year sessions were recorded. The Oxford figures include accidents which occurred during the vacation.

It affects a student population of about 70,000 at British universities, in addition to the large number at technical and training colleges

SUMMARY

1 Accident caused 17 of 35 undergraduate deaths at Oxford University in the three years 1947–49

2 Suicide accounted for 9 undergraduate deaths (during both term and vacation) A suicide rate calculated from this data gives a significantly higher figure than that for the civilian population of the same age, higher than that for the Registrar General's social classes I and II, and higher than that in the Armed Forces

3 Tuberculosis caused 1 death only, and rheumatic heart-disease none

4. During the same three years 145 undergraduates lost one full term's residence on account of illness

5 Mental illness and nervous breakdown accounted for 52 5%, tuberculosis for 23%, and other conditions for 24 5% The relative importance of mental disorder and tuberculosis among students has not received general recognition in the past

6 Two thirds of those who lost a full term's residence because of mental illness and nervous breakdown returned later to continue their university course.

7 In the absence of earlier records there is no evidence of an alteration in mortality rates or in the actual or relative frequency of particular causes of prolonged illness

8 There appears to be ample justification for further and more detailed investigation into the mental health of students and the prevention of mental disorder

I am indebted to various health officers for discussion on this subject and to Dr A. H. T Robb-Smith for advice on the method of survey The university kindly supplied figures from which the population at risk was calculated My special thanks are due to colleagues on the staff of the institute, to Mrs C C Standley for checking the analysis of returns, to Dr W T Russell and Dr L Sutherland for statistical advice, and to Dr Alice Stewart for various helpful suggestions

EDUCATION ON ALCOHOLISM

FORBES CHESTON *

IN the U S A the National Committee for Education on Alcoholism was founded in October, 1944 For the first five years, as the fifth division of the Yale Plan on Alcohol it existed under the sponsorship of the laboratory of applied physiology of Yale University, but just over a year ago this connection was severed The committee now known as the National Committee on Alcoholism, has reached the maturity of independence as a public health organisation

The committee was formed because of general ignorance about alcoholism As Mr Yvelin Gardner, acting executive director of the committee remarked in his report for 1949 [1]

> "The mantle of stigma covered the subject. Constructive action on the part of individuals alcoholics or others, was still spotty and isolated largely because of lack of knowledge of where to go or what to do, and the shame attendant on everything concerning alcoholism. The therapeutic professions were almost entirely unconcerned with the problem. Governmental activity was limited to punishment in jails and in a few hospitals, to temporary 'drying out' techniques not related to any treatment of the condition '

It was felt that unless people learned at least some of the facts, nothing at all would be done The original aim was to disseminate the findings of the other divisions of the Yale Plan, presenting these in a form understandable by everyone, and now the committee seeks by education to mobilise public opinion for action on the problem The committee's educational work rests on three concepts (1) that alcoholism is a disease and the alcoholic a sick person, (2) that the alcoholic can be helped and is worth helping, and (3) that this is a public health problem and therefore a public responsibility

When the N C E A officially announced the opening of its New York offices, everyone of the nine daily newspapers of New York City carried the story Within a few days the news had spread all over the country and mail began to pour in Mr Dwight Anderson, executive director of the Medical Society of the State of New York wrote

> ' Looking back ten years we realise that the idea that the alcoholic was an utterly hopeless person was practically universal, not only among the public, but among the medical profession as well Today the public is ready for educational work on a broad scale such as the National Committee is to take It is the beginning of a new public health movement It is the first step towards getting the alcoholic out of gaol and into hospital towards making it possible for the medical man and the psychiatrist, the social worker and the lay therapist to pool their skills in modifying the ravages of an illness to which society has been indifferent almost to this very moment '

In September, 1946, just two years after the founding of the committee, Mrs Marty Mann, its executive director, stated that 14 cities in the U S A had formed representative citizens' committees, affiliated with the national committee, and that these committees had already launched programmes of community action, and she pointed out that this type of coordinated organisation reduced the problem to a more manageable scale Mrs Mann noted that ' our stated primary aim, that of arousing public interest in the problem of alcoholism, seems well on the way to achievement ", and she quoted her own final words in the March of Time film *Problem Drinkers* "The problem of alcoholism can be solved by a plan of community action The National Committee stands ready to help your community to plan such action "

In the years since 1946 the function of the National Committee has changed from one of stimulation to one of guidance The annual report for 1949 showed the great expansion which had taken place The number of affiliated committees had risen to over 50, and clinical and hospital facilities and information centres had been established in many cities. There were now 22 State-sponsored programmes on alcoholism, developed from the work and guidance of the national committee.

Industry too, is beginning to acknowledge that it has a costly problem on its hands Several major industries have disclosed programmes undertaken on the premise that alcoholics are sick people who can be rehabilitated The Consolidated Edison Company of New York has revealed that it is now pensioning chronic alcoholics where the employee has long been with the company and medical study indicates a compulsive urge to drink Du Pont de Nemours & Company has announced through its medical director that over one hundred valued employees have been restored to the company through the initiation of a programme which recognised and treated alcoholism as an illness In Wisconsin a pro to academic life was stressed at the inquests Pre war figures are not available for British universities, but the University of Michigan (1945) published student death-rates from 1913 to 1942, during which period suicide caused about 15% of all deaths, accident 35%, and illness 50% † At the University of Michigan, where the average annual entry was 11,614, Raphael et al (1937) found that suicide or the possibility of suicide was deemed an important element in 313 students who had attended the mental hygiene unit of the university health service during the previous five years At Harvard, where the entry in 1939–40 was 6400, there were 6 deaths, including 2 by suicide in that year At Yale, where the annual entry was about 5000, Fry and Rostow (1942) reported 8 deaths from suicide in the ten years following 1924 In fact, the importance of suicide was recognised by university health services in the U S.A before the second world war

PROLONGED ILLNESS

The total number of undergraduates who missed at least one full term's residence through illness was 145 (113 men, 32 women) Tuberculosis and mental illness (which are discussed below) were responsible for 23% and 52 5% respectively In the remaining 24 5% the causes of absence included epilepsy, jaundice, asthma, peptic ulcer, concussion, accident, appendicitis, war wounds, and tropical diseases

Tuberculosis—33 undergraduates (28 men, 5 women) lost a term or more on account of tuberculosis during the three years under review It may be assumed that this absence was caused by serious illness, and was not due to minimal lesions detected by mass radiography, the latter was performed at only three colleges and their 6 cases each required at least three months' bed rest, or hospital or sanatorium treatment

Mental illness and nervous breakdown—Of the 76 absent for not less than a term, 49 (64 5%) returned to college, 16 (21%) went down without a degree not to return, and 11 (14 5%) went down but their future is undecided 9 (12%) were stated to have been in a mental hospital or to have been diagnosed as schizophrenia Of these 3 returned to college, and 2 others were said to have been cured, although they did not return

The returns show that mental illness, including nervous breakdown, was responsible for just over half the illness, serious enough to cause absence for at least a full term

However, it has already been stated that, owing to certain factors connected with the method of survey, the morbidity figures probably fall short of the truth As far as the mental cases are concerned, there are further reasons for this belief The 9 suicides are not included in the total, nor is there any information about the attempted but unsuccessful suicides which are known to have occurred in the university Several nervous breakdowns were precipitated by pre examination stress, and, in the case of any breakdown occurring towards the end of term, and in particular the Trinity Term, at least two months were available for mental rest and recovery without loss of a term's residence Then, there are other forms of serious mental disturbance involving extreme problems of discipline or behaviour, deep anxieties, obsessions, or ideas of persecution which do not entail absence from college Fry and Rostow (1942), after ten years' experience at Yale, noted that 16 of their 116 serious cases did not require to leave college at all, and 12 others required only a short period of hospital or other care In fact, it may be estimated that not less than 0 5% and probably nearer 1% of the undergraduate population in residence each year at Oxford suffers some serious form of mental illness or nervous breakdown

For many years enlightened college authorities and college doctors have been convinced of the importance of mental hygiene When, however, the question of preventive action is discussed there is a general feeling that "common sense" is an adequate tool for handling the problem, and no special measures are required. Those interested in the mental welfare of students are thought to be prejudiced, and their personal experience unrepresentative I found from routine health examinations that psychological disturbances, although mostly of a minor character, were unduly common (Parnell 1947), but the significance of the finding, was doubtful. It might have been due to the excessive thoroughness of the examination, or possibly even to the over sympathetic outlook of the examiner It was the need for objective confirmation of a clinical impression which first prompted this objective survey, which shows that mental disorder is the principal cause of prolonged illness

In these circumstances it is natural to ask what preventive steps might be taken, although no scheme is likely to prevent all forms of psychosis

Preventive measures need not and should not pay too much attention to individuals They should not involve healthy young men in routine psycho analysis, nor need they, in a popular but ugly phrase, "stir up the mind" unnecessarily They need not provoke hypochondria or encourage introspection, nor need they sap self reliance or engender a feeble and dependent state of mind Serious opposition to the adoption of preventive measures is founded on the alleged ineffectiveness of individual methods Close tutorial supervision, with particular attention to the early signs of mental staleness and cumulative fatigue, should help Better individual instruction in the principles of mental hygiene, in particular in the optimum hours of work, is also required, and it would be desirable to have a doctor or psychiatrist well versed in college life readily accessible for consultation There is evidence that less severe forms of mental or nervous disorder are more common than the severe forms discussed so far, and the preventive measures suggested apply to them with equal force

In war, inactivity because of uncertainty about the technique of victory is inexcusable So too, in the fight against mental ill health preventive measures should not wait indefinitely upon the improbable discovery of some new technical device for early detection On the other hand whatever action is contemplated in the light of present knowledge, it is clear that further and more detailed study of the problem is urgently needed

DISCUSSION

The question will certainly be asked whether this paper draws attention to a state of affairs long present but hitherto unrecognised, or whether there has been a recent increase in the prevalence of mental disorder Since no report has been discovered of any previous survey on these lines, precise evidence on this point is lacking The gravity of the position may not have been recognised because the undergraduates with tuberculosis, mental illness, and the like have been treated by a number of different departments In any event, it is clearly desirable that the facts should be widely known

At a recent conference student health officers expressed concern at the absence of precise information on the incidence of mental ill health among students To remedy this, and to make comparative study possible between universities, some uniform system of recording serious and prolonged illness is clearly desirable Preliminary work to establish such a system is now advanced, and it is reasonable to hope that before long it will be ready

---

† Only deaths occurring during the nine months per-year sessions were recorded The Oxford figures include accidents which occurred during the vacation

General practitioners not in the dispensary service did not come under the scheme as first proposed, except in so far as they might be absorbed into it when new appointments were being made. Compensation for loss of practice was not mentioned; but, after protests, the minister intimated that he was prepared to allow general practitioners to enter the scheme if a sufficient number applied to do so.

Not unnaturally these proposals, changing almost the entire basis of medical practice in Ireland, have been closely scrutinised by the Irish Medical Association and by the profession generally. The response to the scheme cannot be regarded as enthusiastic. In the first place it is regarded as a long step, without any prior consultation, towards a completely salaried profession. With a ringside view of the British experiment—possibly more attractive—few practitioners in Ireland desire to copy it.

Secondly, on the basis of British figures, the I.M.A. has estimated that the scheme would cost not less than £12 million annually. This figure may not seem exorbitant, and may even appear fantastically cheap to English eyes, until it is realised that the Irish budget is of the order of £83 million.

The third ground of criticism bears on the implied charge that the profession has failed in its duty of effectively lowering the infant mortality rate. In a brochure just issued to the public the rate is given as 53 per 1000—the 1949 figure. The 1947 figure was 68, and that for 1950 was 45. The I.M.A. claims that further substantial reductions can only come from a wider approach through better housing, nutrition, and hygiene. Even though the maternal mortality rate has been reduced to 1.9 per 1000 births, far more maternity hospital beds are also needed.

All are agreed, however, that some form of assistance is required to meet the cost of modern medicine. The I.M.A., acting on the principle that "preventive, consultant and ancillary services should be provided for all immediately—free for the poor, assisted for the middle income groups and paid for by the rich," has proposed a grant in aid scheme. This has been rejected by the minister on the ground that it involves a means test, to which he is adamantly opposed. He says that he is willing to meet the association providing the means test is not in question. In an effort to end the deadlock the association has offered to discuss health services generally, without prior conditions, through a joint committee presided over by a neutral chairman.

Medical opposition to the scheme is hardening. Both the private practitioners' and the dispensary medical officers' groups of the I.M.A. have declared against it. The minister has probably the power to compel the latter group to operate the scheme—but compulsion has never been a very satisfactory weapon in Ireland! Differences have so far dominated the picture, and the fact that both parties agree that a scheme of some kind is necessary has been overlooked. If a way out of the impasse is to be found concessions will have to be made by both sides.

Public Health

POLIOMYELITIS IN SEMI-CLOSED COMMUNITIES

A. H. GALE
D.M. Oxfd, D.P.H.
LECTURER IN EPIDEMIOLOGY, UNIVERSITY OF BRISTOL; LATELY A SENIOR MEDICAL OFFICER, MINISTRY OF HEALTH

A COMPARATIVE study has been made of the epidemiology of poliomyelitis in camps, residential schools, and other semi-closed communities. In addition to published accounts of such outbreaks unpublished accounts in the records of the Ministry of Health have been used, and school doctors have very willingly helped both by furnishing accounts of hitherto undescribed incidents and by supplementing the information which already existed in published papers or in the records of the Ministry.

The last similar survey in this country was published by Smith (1939), and all the outbreaks described by him have been included with many others. Usually only those outbreaks in which more than one paralytic case occurred have been included, but exceptions have been made where detailed descriptions of the sequence of events were available and these seemed to be of special interest. Names of schools have been omitted throughout because of the danger of causing embarrassment to the school authorities, but the name of the county in which the school was situated is given.

One of the difficulties has been that the reports vary a great deal in their method of presentation, in the amount of detail given, and in the nomenclature of the various types of case. So far as possible, the different accounts have been reduced to a common nomenclature. "Epidemic" means a fairly widespread prevalence in a group of communities or in the country as a whole, and "outbreak" the experience of a single community. For convenience of description and of diagrammatic representation the outbreaks have been grouped as follow:

(1) Four outbreaks in camps for boys.

(2) Three outbreaks in children's homes.

(3) The epidemic in Broadstairs, Kent, in 1926 (Ministry of Health 1926, Aycock 1927, Watts 1927).

(4) Sixteen outbreaks in residential schools and one in an American University reported in 1917–45. The Broadstairs schools are excluded from this group, but another school which experienced an outbreak in 1926 is included.

(5) Thirteen outbreaks in residential schools in England and Wales in 1947–49. These are discussed separately from those of group 4 because the very high prevalence in the country as a whole in 1947 and 1949 was a new experience.

(6) A miscellaneous group of outbreaks which did not fall into any of the other groups but occurred in semi-closed communities. These did not lend themselves to diagrammatic representation.

Figs. 1–5 show the time relations of the onsets of cases in groups 1–5. The same symbols have been used throughout, but fig. 1 shows the history of the illness in each case, whereas figs. 2–5 show only the time relations of the onsets of cases. It is only in the outbreaks in the U.S.A. that the distribution of virus has been investigated in detail.

CAMPS (FIG. 1)

(1) *Detroit* (Brown et al. 1945).—There were 2 paralytic cases among a group of 10 boys, aged 13–17, in one cabin; 4 healthy boys in the same cabin had virus in their stools. Stools from 10 boys in the next cabin were all negative. Messing arrangements were common to the whole camp.

(2) *Massachusetts* (Rubenstein et al. 1948).—There were 5 cases (4 bulbar, with 1 death) among 31 boys, aged 13–17, in one group out of three. The groups slept in small tents 2 boys to a tent. Stools from 7 boys in other groups were negative for virus. Messing arrangements were common to all groups but each group had a separate table.

(3) *Sussex* (Conybeare 1946).—In a large camp of some 1200 scouts there were 6 paralytic cases in a group of 131 boys aged 13–18. 5 of the cases were in a small subgroup of 30 boys. There was 1 associated case in a sister of a boy who had been quite well at camp. There was a good deal of minor illness among the boys in camp. The camp lasted from July 30 to Aug. 10 and for the last week the weather was so bad that the boys had to stay in their tents a good deal during the day.

(4) *West Riding of Yorkshire* (unpublished).—There were 2 paralytic cases and 1 non-paralytic among 18 boys and 1

gramme embracing more than a dozen large companies working in conjunction with the State programme on alcoholism is being conducted with the cooperation of the national committee

Perhaps the most important statement in the 1949 report comes under the heading "legislation" The report says

> "The intensive campaign on alcoholism during the past few years has resulted in a definite trend toward State legislation with respect to the treatment and cure of the alcoholic Approximately three fourths of the State legislatures considered some type of legislation on alcoholism during the 1949 sessions Committees, commissions, groups, governmental bodies, and individuals from most of these States turned to the National Committee on Alcoholism for education and guidance "

In December, 1950, a W H O expert subcommittee on alcoholism as a public health problem met in Geneva After defining alcoholism, the subcommittee recommended that its prevention and treatment should become a regular function of public health administrations, and that it should be treated on medical and scientific lines, as opposed to the approach of lay reform Treatment facilities and advisory, educational, and other services should be provided The subcommittee sugggested that efforts be made to uncover early cases of alcoholism, where treatment was most likely to succeed Outpatient clinics were necessary, and were best situated in well equipped general hospitals If adequate networks of such clinics were to be developed, the need for specialised residential institutions for alcoholics would progressively diminish The subcommittee indicated the extreme variation in social drinking customs in different countries, and pointed out that the per caput level of alcoholic consumption in a country was no certain evidence of the incidence of alcoholism in that country It urged the development of national statistics on this matter in every country Figures were given for the incidence of chronic alcoholism in certain countries, the number of chronic alcoholics in England and Wales was said to be 86,000 †

In a broadsheet *Facts on Alcoholism*, published by the National Committee on Alcoholism, the following statements occur

> At least 12 000 alcoholics die each year in the States from chronic alcoholism
>
> Five out of six alcoholics are men between the ages of 30 and 55—the most productive years
>
> Every industry, every business, every profession, every community suffers from this problem
>
> Present methods of dealing with the problem of alcoholism are in very many cases expensive, sometimes barbaric, and often do not rehabilitate or prevent
>
> A majority of alcoholics can be rehabilitated

These statements apply to America, but the problem exists in this country and cannot be ignored It may be a smaller problem, but, apart from numerical differences, all these statements undoubtedly apply here In America the National Committee on Alcoholism has provided communities and the professions, industries, and businesses involved with the medical, scientific, and practical knowledge needed to rehabilitate the alcoholic and to prevent alcoholism Can this country afford to ignore the problem of this disease, which is costing us thousands of man hours in industry and thousands of pounds in money, and which has a very high rate of mortality ?

RESEARCH AND TEACHING IN NEW ZEALAND

FROM OUR NEW ZEALAND CORRESPONDENT

THE following members have been appointed to the newly incorporated Medical Research Council of New Zealand

Ex officio Dr John Cairney, director general of health (chairman), Sir Charles Hercus, dean of the medical faculty, Otago University, and Mr F R Callaghan, secretary of the Council of Scientific and Industrial Research

Appointed Sir James Elliott (on recommendation of the board of health), Dr P P Lynch (British Medical Association), Dr L Bastings (Royal Society of New Zealand), Dr R S Aitken, Dr F Walsh (academic board of the senate of the University of New Zealand), Prof F H Smirk (New Zealand committee of the Royal Australasian College of Physicians), and Mr Douglas Robb (New Zealand committee of the Royal Australasian College of Surgeons)

The council's first meeting is to be held in May

Postgraduate course in obstetrics at Auckland—The first major educational effort of the new foundation for postgraduate studies under Auckland University College was a fortnight's postgraduate course in obstetrics and gynæcology, held between March 5 and 16 Pending an appointment to the chair of obstetrics, the course was organised by Sir Bernard Dawson, who has lately retired from the chair at Otago University Sir William Gilliatt's visit to inaugurate the New Zealand regional council of the Royal College of Obstetricians and Gynæcologists coincided with the course, and he participated in lectures and discussions

FREE MEDICAL CARE OF MOTHER AND CHILD

FROM OUR DUBLIN CORRESPONDENT

MUCH discussion among the profession in Ireland has been engendered by the proposals of the minister for health, Dr N C Browne, for a comprehensive Mother and Child Welfare Service based on part III of the Health Act, 1947.

Popularly known as the Mother and Child Scheme, this is to provide free medical and nursing care for all mothers "before, during, and after childbirth," and for all children up to the age of 16 years Mothers are to receive free family practitioner, specialist, consultant, and hospital treatment, domiciliary visits from midwives, and also dental and ophthalmological treatment All children under the age of 16 years are to be eligible for free medical care for all illnesses, free specialist, consultant, surgical, and hospital treatment, visits from public health nurses, and dental and eye treatment While nobody is to be compelled to use the service, it will be completely free for those who do there will be no means test, and in the words of the department of health "there will be no doctor's bills in respect of maternity or the health of children up to the age of 16 " Not only is the scheme to be free, but those availing themselves of it will not have to pay contributions of any kind, whether by means of insurance or otherwise Part III of the Health Act, while giving the minister power to make regulations as to the manner in which the service is to be set up and carried on, does not in fact enact that it must be free

The working of the service is to be based in the first place on the dispensary doctor—or district medical officer—and the dispensary districts will be modified, new doctors being appointed where necessary By such means there would be, except in some remote areas, a choice of from two to six or more doctors It is stated that the doctor patient relationship will be preserved, but, as the employer will be the local authority, this statement seems rather ingenuous.

---

† According to Dr E M Jellinek secretary of the expert sub committee an approximation of the number of chronic alcoholics for a country can be roughly determined compiled from various sources Mrs Mann (personal communication) remarks The figures Dr Jellinek has released refer only to alcoholics in the most advanced stage To get the number of chronic excessive drinkers, or alcoholics he multiplies that figure by 5 '

was seventeen days There were some abortive cases in all three wards

BROADSTAIRS EPIDEMIC IN 1926 (FIG 3)

Although many schools were affected in this epidemic all were affected at about the same time, and it must be regarded as a single event The institutions affected were as follow

School A, for 73 boys (all boarders), had 12 cases (1 case in a member of the staff)

School B for 21 boys (all boarders), had 5 cases

School C for 24 boys (3 boarders and 21 day boys), had 4 cases (3 in day boys)

School D, for 28 boys (all boarders), had 2 cases

School E for 43 boys (25 boarders, and 18 day boys), had 2 cases in boarders

School F for 74 girls (all boarders), had 2 cases in girls and 2 in members of the staff

School G for 53 girls (all boarders), had 3 cases

School H, for boys and girls (boarders and day pupils), had 6 cases

School I for boys and girls (boarders and day pupils), had 3 cases

Convalescent home X had 1 case in a boy patient

Convalescent home Y had 5 cases, of which the first 2 were in children (patients) and the rest in female members of the staff

An elementary school had 4 cases

Schools A–I were largely for boys and girls up to the age of about 13, but some of the schools had older girls

This epidemic was described by the Ministry of Health (1926) and Aycock (1927) Aycock believed that the infection was milk borne but MacNalty, who investigated the outbreak on behalf of the Ministry of Health, never accepted this view Fig 3 suggests that there were two waves, the first one affecting schools A–I, and the second the convalescent homes and the elementary school There is, however, some overlapping, and it is difficult to be sure on this point Aycock maintained that the whole outbreak could be explained on the hypothesis of a simultaneous infection dating from Oct 10, and that there was a good deal of confusion about dates of onset in the earlier cases In America this outbreak is often cited as definitely milk borne, but this explanation seems doubtful. There was an extraordinarily high attack rate, and the epidemic is of particular interest in that, with one exception (see fig 4), it seems to be the only occasion on which multiple paralytic cases have been reported in boarding-schools for girls (schools F and G were for girls only) This may be due to the fact that outbreaks in schools are comparatively rare and that the number of boarding schools for boys is much greater than that for girls A possible explanation might be, however, that girls at boarding schools are generally sent to bed for rather less serious complaints than are boys and thus have less opportunity of infecting others.

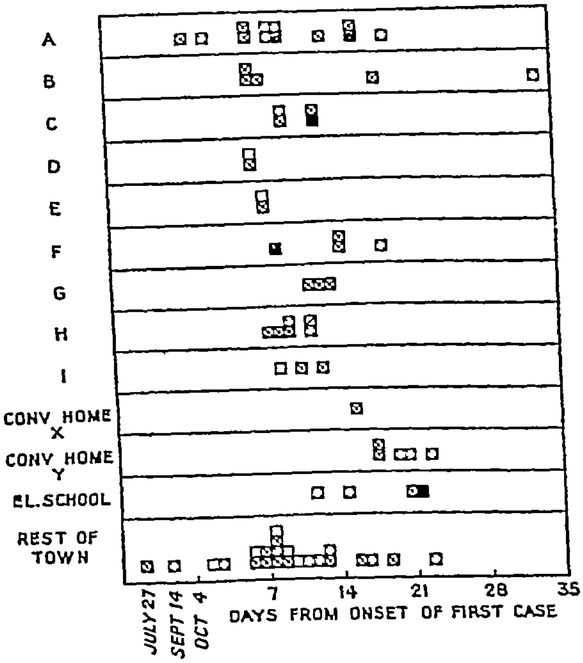

Fig 3—Poliomyelitis at Broadstairs in 1926

RESIDENTIAL SCHOOLS 1917–45 (FIG 4)

The schools concerned were as follows

(1) *Gloucestershire* (Local Government Board 1918)—This school for boys, aged 13–18 had 400 boarders in six houses and 200 day boys There were 3 paralytic cases (1 fatal) in 1917, 2 were in one house and 1 in another

(2) *Berkshire* (Smith 1939)—This school had 350 boys boarded in eight houses The outbreak of 7 cases occurred in the middle of an influenza epidemic in 1918 and seems to have been explosive The cases were in different houses This is the same school as no 16

(3) *Rutland* (Ministry of Health 1926)—This school for 500 boys, aged 13–18, boarded in thirteen houses had 3 cases in different houses in 1926, 1 of them occurred in the holidays

(4) *Kent* (Brown 1931)—This mixed school for boys and girls, aged 6–13 had 56 boarders, 11 teachers, and 8 domestic staff In 1929 there were 2 paralytic cases among the children (1 fatal), 2 cases with nasal voice but no other signs of paralysis and 1 non paralytic case in a member of the staff. 1 child developed nystagmus and nasal voice sixteen days after the dispersal of the school All the paralytic cases had cranial nerves alone affected

(5) *Mid western College U S A* (Rosenow 1932)—479 male and 448 female students lived in six dormitories on the campus and had a common dining room There were 8 cases in 1930 Dates of onset are not given. Rosenow considered that a streptococcus was responsible

(6) *Dorset* (unpublished)—This school of 370 boys aged 13–18 had a small catarrhal wave at the beginning of the Michælmas term in 1932 The 2 cases were in different houses and forms Six boarding houses and one day boys' house shared a common dining room. This school is the same as no 28 (fig 5)

(7) *West Riding of Yorkshire* (unpublished)—This school of 88 male boarders aged 10–18 had 7 cases in 1933 There had not been any illness at all up to June 10 The boys lived in two houses both of which were affected. The boys used a common dining room

(8) *Herefordshire* (unpublished)—This school of 91 boys (49 boarders and 42 day boys), aged 9–19 had 2 cases in 1933 There were two dormitories in one building with common dining arrangements Both dormitories had a case

(9) *Boston, Mass* (Aycock 1942)—This American school of 190 boys aged 13–18, had 18 cases in 1936 No details are given of dormitories or dining rooms

(10) *Devon* (unpublished)—This school for a few boys, aged 8–13, had 3 cases in 1937 The first outside case was in the brother of a boy taken ill at school on Sept 25 The fatal outside case (onset Oct 14) was in the sister of a boy who went home from school on Sept 25 for two days and again on Oct 7 He had had a slight bilious attack at school on Sept 22

(11) *Essex* (Barber 1938)—This school of 400 boys aged 13–18 boarded in four houses in the main school and two outside, had 4 cases in 1938 All the cases were in the same house and 2 of them in the same dormitory

(12) *Essex* (Gammie 1939)—This school of 284 boys, aged 9–18, had 214 boarders in four houses and a preparatory department, and 70 day boys In 1938 there were 4 cases It is not stated definitely whether all the cases were in one house, but it seems that at least 2 in boys and 1 in a maid were

(13) *Berkshire* (Lambert 1939)—This boys' school of 670 boarders, aged 13–18, had 3 cases in 1938 The main building

young scoutmaster living in five tents One of the paralytic cases was fatal

These four outbreaks are particularly interesting because the limits of the period in which infection probably took place are better defined than they are in most outbreaks In the Detroit and Massachusetts outbreaks virus studies were done One of the cases in the Detroit outbreak is often cited because virus was found in the stools nineteen days before the onset of paralysis In both outbreaks there was evidence that at an early stage virus was widely disseminated within the affected group but had not spread outside that group

Fig 1 illustrates the difficulty of working out the chronology of infection from the dates of onset of cases This point has been made by Horstmann and Paul (1947) The case associated with the Sussex camp was in the sister of a boy who attended the camp but had no illness either at the camp or afterwards The minor illnesses which affected at least 15 boys while they were at the camp were not definitely diagnosed They might have been illnesses of infection, but that in case 1 was probably an illness of onset Possibly some of the boys in this outbreak were infected after they got home from the camp, but this does not seem very likely

In the West Riding outbreak the weather was good and the only incident of note during the camp was that on Aug 27 one boy (case 2) had a headache which lasted about half an hour It is uncertain which was the source case The sequence of events in this outbreak was very different from that in the Sussex outbreak In Sussex the onsets of paralysis were scattered over about a month after the end of the camp, whereas in Yorkshire the scoutmaster was dead, one boy had a quadriplegia, and another signs of meningeal irritation, all within twelve days of the end of the camp

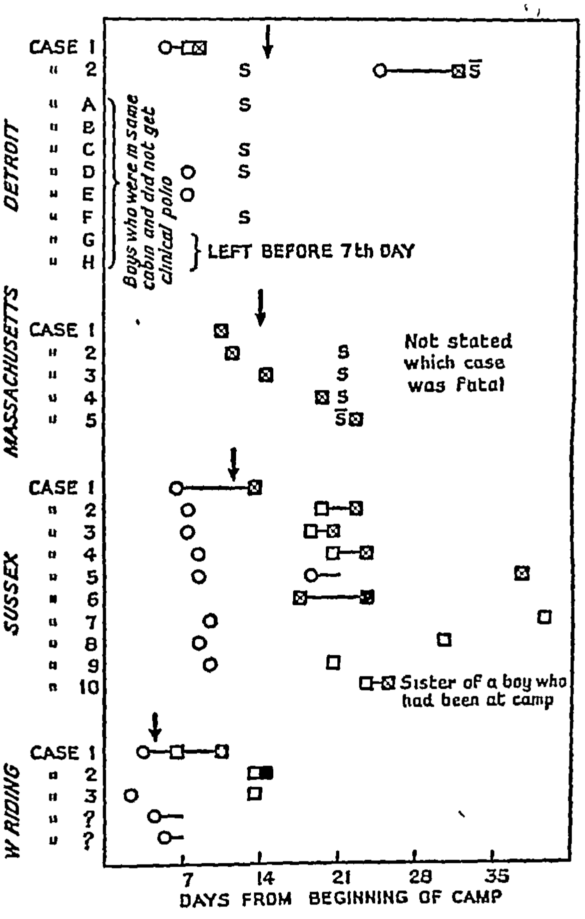

Fig 1—Poliomyelitis in camps.

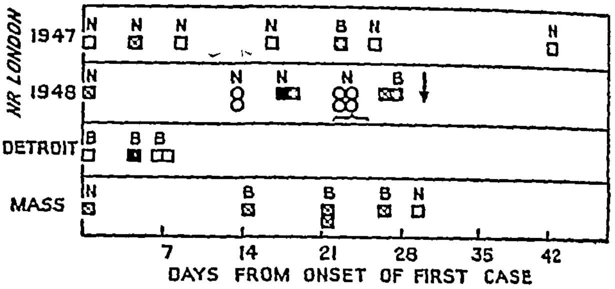

Fig 2—Poliomyelitis in children's homes.

Daley (1948) reported that, when the epidemic of 1947 was at its height in London, 1 case occurred in a party of 240 secondary school children who went into camp at the end of July, and 3 cases occurred in the party which followed on Aug 9 It seemed clear that all these children were already infected when they arrived at the camp, and that no spread took place in the camp Everyone was on the alert for poliomyelitis at the time, and all the patients were promptly isolated These two incidents are not shown in Fig 1

CHILDREN'S HOMES (FIG 2)

(1) *Near London* (Daley 1948)—This home contained 125 children under the age of 5 years, and a staff consisting mostly of adolescent girls In July, 1947, there were 1 paralytic and 5 non paralytic cases among the staff, and only 1 case in a baby (aged 14 months) There was a good deal of minor illness among the staff and later some cases of infectious hepatitis occurred among them but not among the children

(2) *Near London* (unpublished)—This home contained 34 children under the age of 5 years, 63 young adult girl trainees, and 15 resident and 3 non resident older staff In July, 1948 there were 3 paralytic cases in young adult girls 1 fatal case in a member of the staff aged 31, and 1 paralytic case in a baby aged 8 months

(3) *Detroit* (Kramer et al 1939)—This home contained 10 children under the age of 5 years, 14 children aged 5–16, and a staff of 17 There were 1 fatal and 3 non paralytic cases among the children in August, 1939 Stools from 5 unaffected children and 1 member of the staff were positive for virus on Aug 11, and 2 were still positive nineteen days later

(4) *Massachusetts* (Silverman 1941)—This home was in two sections an orphanage of 117 children under the age of 6 years, and a hospital section with 17 children of all ages in it The preschool and hospital sections (49 children and 23 staff) had 5 cases in March, 1939 The adults of the two main sections had contact with each other, but the children were kept separate The first case was a paralytic one in a nursemaid in the orphanage 4 infants, of whom 3 were in the hospital had paralytic attacks, and 1 adult, who worked in the laundry, had a non paralytic attack. This adult was in the habit of visiting her baby in the orphanage Virus studies were done, but the results obtained by different workers were contradictory

The first and second outbreaks near London were regarded as unusual at the time of their occurrence in that all the cases except two, one in each, occurred among the staff—mostly young women aged 18–30

Another outbreak (Bloomberg and Barenberg 1924), not shown in fig 2, occurred in a home for 300 infants aged from 6 months to 2 years There were 10 paralytic cases—5 in one ward, 4 in a second, and 1 in a third 6 cases occurred within a day or two of one another, and the longest interval between cases in the same ward

boys), had 3 cases in 1947 affecting two masters and one boy The mother of a day boy also developed paralytic poliomyelitis on July 12 Her two children had slight attacks of vomiting on July 14 Four day boys had minor illnesses between July 13 and July 20, but on the whole there was little minor illness in the school.

(22) *Warwickshire* (unpublished)—This school of 600 boys aged 13–18 (550 boarders and 50 day boys), had 4 cases in 1947 This was a public school with ten separate boarding houses All the cases were in one house and nearly all in one dormitory 2 cases occurred in the summer holidays There were 8 cases of minor illness in the same house between July 2 and July 24

(23) *Berkshire* (unpublished)—This school of 99 boys aged 8–13 (all boarders) had 4 cases in 1947 1 case occurred on the last day of term and 1 paralytic and 2 non paralytic in the holidays The boy who had developed the disease first had been in the sanatorium with bronchitis and asthma for a week before the onset of poliomyelitis

(24) *Cornwall* (unpublished)—This school of 360 boys aged 12–18 (215 boarders and 145 day boys) had 2 fatal cases in 1948 They were in separate houses which had a common dining room.

(25) *West Riding* (unpublished)—This school of 400 boys, aged 13–18 (all boarders living in seven houses), had 4 cases in 1948 3 cases were in one house and 1 in another but the last was in the same class as one of the earlier ones There was unusual prevalence of minor illness at the time

(26) *Middlesex* (unpublished)—This school of 520 boys aged 13–18 living in eleven houses had 3 cases in three different houses in 1948 There was an epidemic of sore throats in the school at the time

(27) *Buckinghamshire* (unpublished)—This school of 183 boys aged 8–13 (60 boarders and 123 day boys all in one building) had 3 cases in 1948 An associated case occurred in a dental attendant employed by the dentist who looked after the school Several boys and masters visited the dentist when virus was presumably widespread among them. There were other cases in the neighbourhood at the time

(28) *Dorset* (unpublished)—This school of 400 boys, aged 13–18 (350 boarders and 50 day boys in six houses plus a day boys house with a common dining room) had 7 cases in 1949 There were 3 cases in one house and several cases of minor illness This is the same school as no 6

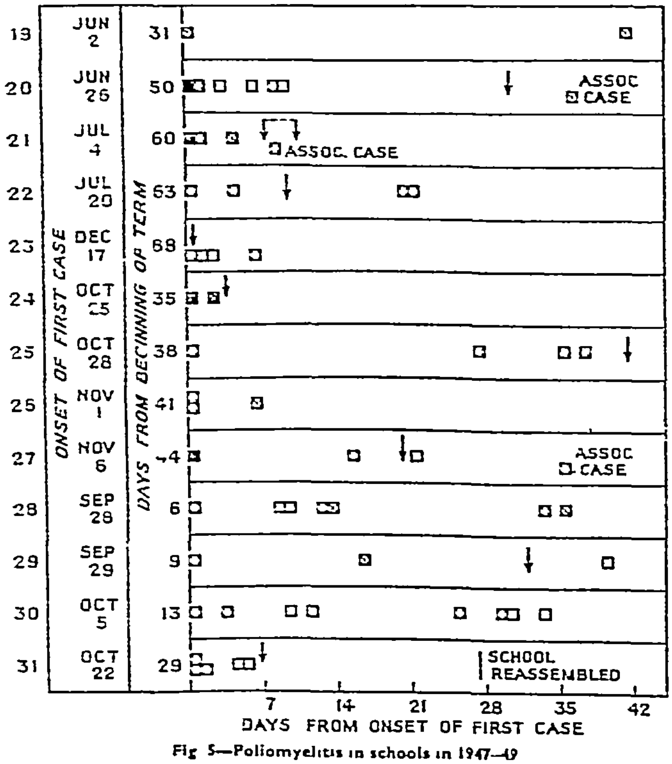

Fig 5—Poliomyelitis in schools in 1947–49

(29) *Hampshire* (unpublished)—This school of 49 boys aged 6–13 (42 boarders and 7 day boys), had 3 cases in 1949 One boy developed a non paralytic attack at home in the subsequent holidays There were 19 cases of minor illness (headache, vomiting &c) between Oct 7 and Oct. 27

(30) *Huntingdon* (unpublished)—This school of 81 boys, aged 7–13, and living in two houses but with a common dining-room, had 8 cases spread between both houses in 1949 There were a few cases of minor illness

(31) *Lancashire* (unpublished)—This school of 400 boys aged 7–18 (mostly boarders in eight houses with a common dining room and two separate ones), had 5 cases in 1949 Cases occurred in the main block and in the separate junior school The school was disbanded for three weeks and then reassembled No further cases occurred after reassembly

These twelve outbreaks (nos 19–30) have been grouped together because the incidence of poliomyelitis was so much higher in the country as a whole than it had ever been that importation of infection into a school was an almost continuous risk.

Minor illnesses have been omitted from fig 5 because in some outbreaks so many were reported that the diagrams would have become confusing

As in the outbreaks in schools in 1917–45, the epidemiological pattern varied greatly, from that exemplified in school 24, with 2 fatal cases in three days and no more, to that exemplified in school 28, in which the onset of the first case was right at the beginning of term and further cases occurred throughout the term It is again difficult to find any definite association between the type of school and the duration of the outbreak Schools 19, 22, 25, 26, 28, and 31 were large public schools run on the house system, schools 24 and 30 were of intermediate type with two boarding-houses, and schools 20, 21, 23, 27 and 29 were preparatory schools in which all the boys lived in one building In school 22 all the cases occurred in one house, but in school 26 the cases were all in different houses, though all occurred within a week of one another In school 19 there were 2 cases, with nearly six weeks between, in different houses and apparently unassociated

Associated Cases—In School 20 the associated case (onset Aug 1) was in the small brother, aged 3½ years, of a boy who had returned home from school on July 26 In school 21 the associated case was in the mother of a day boy In school 27 the associated case was in a dental nurse employed by the dentist who attended the masters and boys Her illness began on Dec 13 Masters or boys had visited the dentist on Nov 25 Dec 2, and Dec 9

Time of Year—Nine of the outbreaks occurred in the autumn and four (all in 1947) in the summer term It is perhaps worthy of note that in 1947, in the country as a whole, incidence began to rise earlier than usual and, although the peak of incidence was much higher in 1947 than in 1949 and very much higher than in 1948, the peak was sharper than it was in 1948 and 1949

SINGLE PARALYTIC CASES IN SCHOOLS

We know less about the occurrence of single paralytic cases than about the occurrence of multiple cases because very naturally, everyone heaves a sigh of relief when only one paralytic case occurs and does not consider the incident worth reporting This is a pity since negative evidence might be just as interesting from the epidemiological point of view as positive evidence

The Medical Officers of Schools Association (Smith 1939) obtained incomplete information from fifty one schools for 1912–32 No cases were reported from ten girls' public schools or from eleven preparatory schools Of thirty boys public schools eleven had no cases and with about 450 boys was divided into ten dormitories with a common dining hall. The other 220 boys lived in four outside boarding houses. Cases occurred in boys from nine out of ten dormitories in the main building; 15 (some abortive) occurred in the holidays, and one boy infected a brother (also a member of the school) after dispersal.

(14) *Durham* (unpublished).—This school of 300 boys, aged 11–18 (200 boarders and 100 day boys), had 6 cases in 1944. Cases 1–4 and 6 were in boarders, and case 5 in a day boy. The boarders lived in one building with one dining room.

(15) *Oxfordshire* (unpublished).—This school of 360 boys had 3 cases in 1944. All the cases were in different houses, and the last was in a boy in the preparatory house, members of which have contact with the boys in the *main school in the dining room only*.

(16) *Berkshire* (unpublished).—This boys' school of 300 boarders had 8 cases in 1945. There were two groups of buildings: (1) The college (divided into three houses) and two outside boarding houses, with a common dining room for 200 boys; and (2) two houses in one building with a common dining room for 100 boys. Cases occurred in both groups, but only 1 in the second group of buildings, and there is evidence that the college and one of the associated houses were affected first. There was an outside case in a baby not closely connected with the school. This is the only school outbreak which I have been able to find occurring so early as March. The school is the same as school no. 2.

(17) *Hampshire* (Ministry of Health 1945).—This school of 132 boys (43 boarders and 89 day boys) had 6 cases in 1945. There were 5 cases with paralysis: 1 was in a boarder, 2 in day boys, 1 in the infant sister of a day boy, and 1 (fatal) in an adult living in the same house as three day boys, none of *whom was ill*.

(18) *Devon*.—A girls' boarding school had 2 cases in 1937.

It has been impossible to check the details of the outbreaks shown in fig. 4, and the number of cases of minor illness and the exact dates of onset were often doubtful. If only paralytic cases are considered, fourteen of the outbreaks were over in a fortnight so far as the school itself was concerned. The outbreaks in schools 4, 14, and 15 lasted longer. There seems to be no definite association between the length of an outbreak and any particular type of school. The outbreak in school 4 was unusual in that, in the cases with paralysis, only cranial nerves were affected (Brown 1931).

Associated cases have been shown only when the association with a member of the school was a close one. In school 10 the first case was in a boy taken ill on the day before he should have returned to school. His brother (the second case shown) fell ill five days later at school. The fatal case was in the sister of a boy who was at the school and returned home seven days before the onset of his sister's illness. In school 17 the 2 associated paralytic cases occurred in the infant sister of a day boy and in an adult (a fatal case) who lived in the same house as three of the day boys, none of whom was ill. It is impossible to be sure that the apparent source of infection of the associated cases was the true one, but it is noteworthy that in all instances the infection was apparently conveyed by a healthy carrier.

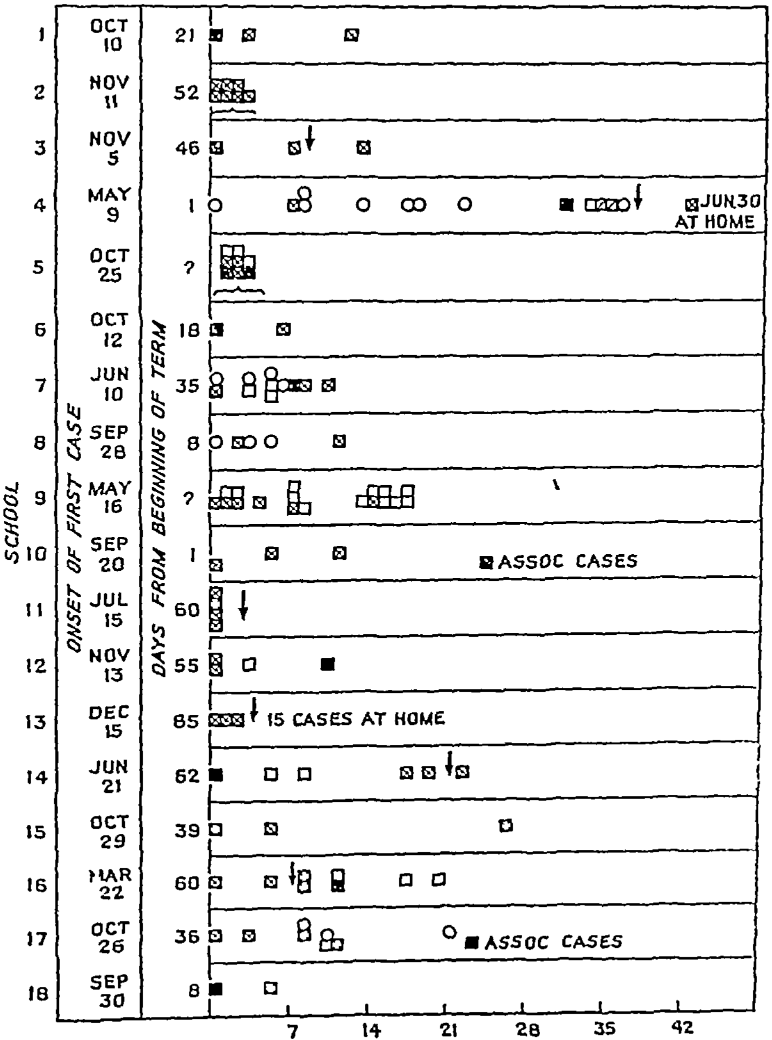

Fig 4—Poliomyelitis in schools in 1917–45

Building Arrangements.—Ten of the outbreaks occurred in schools run on the house system or modifications of it. In school 15 all the boys affected were in one house, and two were in one dormitory. In schools 7, 13, and 16 the cases occured only in a group of houses with a common dining room. In school 15 the last case occurred in the preparatory department, the members of which met boys of the senior school only in the dining hall. In the remaining outbreaks cases occured in different houses. There is no very convincing evidence that an outbreak tends at first to be confined to one house or group of houses, but there is a suggestion that it does.

Time of Year.—Twelve of the eighteen outbreaks were in the autumn term, five in the summer term, and one in the Easter term. There does not seem to be any stage of the term at which an outbreak is particularly liable to begin.

RESIDENTIAL SCHOOLS 1947–49 (FIG. 5)

(19) *Dorset* (unpublished).—This school of 506 boys aged 13–18 (502 boarders and 4 day boys), in 1947, had 2 cases in separate houses with no apparent connection between them. There was no remarkable incidence of minor illnesses in the school.

(20) *Dorset* (unpublished).—This school of 65 boys, aged 8–13 (all boarders), had 6 cases in 1947. All the boys lived in one house. Between June 15 and June 23 many boys had complained of minor illnesses—sore throats and headaches—and some had vomited. The date of onset of the first case was June 26 and the boy died on July 4 in coma without developing definite paralysis. Many boys went home at the beginning of July, but some remained until the end of term on July 20. On Aug. 1, the younger brother aged $3^1/_2$ years, of one of the boys who had returned from the school developed paralytic poliomyelitis. The schoolboy had had no illness either at school or after his return home.

(21) *Hertfordshire* (unpublished).—This school of 97 boys aged 8–13 (54 boarders and 13 day

communities in this country Meanwhile the accumulation of purely clinical accounts should go on. If these accounts are detailed and presented in a uniform way, the task of comparing them is made very much easier

Nothing has been said here about the best procedure to adopt in face of an outbreak in a semi closed community, partly because the great variety of form which outbreaks assume makes it impossible to lay down hard and fast rules, and partly because a conference assembled by the Medical Officers of Schools Association (1946) has already issued sound general advice The only recent work which may perhaps be regarded as reinforcing that advice is that of Russell (1947) and Horstmann (1950) on the evil effects of exercise in the early stages of poliomyelitis

SUMMARY

Summaries have been given of four outbreaks of poliomyelitis in school camps, of four in children's homes, of the epidemic in Broadstairs of 1926, and of thirty one outbreaks in boarding-schools reported in 1917–49 An attempt has been made to present these in a uniform way so that comparisons can be made between them

My thanks are due to many past and present members of the medical staff of the Ministry of Health whose reports I have consulted, to fellow members of the Medical Officers of Schools Association, and to Medical Officers of Health who have supplied me with much information hitherto unpublished.

Measles

After a slight decline during the previous week notifications of measles in England and Wales increased sharply during the week ended March 17, when 31,837 cases were reported The position in London and the home counties, recently most heavily infected, was almost unchanged Increases of some size took place in Lancaster, the West Riding of Yorkshire, Southampton, Warwick, and Derby Of the county boroughs Plymouth, with 610 cases, had the highest rate of incidence, and notifications in Birmingham rose to 885, compared with 590 the week before

Whooping-cough

In England and Wales the number of whooping-cough notifications has fallen for two weeks running In the week ended March 17 the total was 5516—121 fewer than in the previous week. The most noteworthy decreases were in Kent and Stafford. Liverpool and Birmingham, with 136 and 105 cases, were again the county boroughs with most cases

Influenza

During the week ended March 17 deaths from influenza in the 126 great towns of England and Wales totalled 88, compared with 130 in the preceding week. This was the lowest total since the week ended Dec. 16, just before the epidemic began Of the 88 deaths, all but 12 were of patients over 55 years of age. The epidemic can now be regarded as ended.

Poliomyelitis

During the week ended March 17 notifications of poliomyelitis in England and Wales were as follows paralytic 18 (9), non-paralytic 0 (4), total 18 (13) Figures for the previous week are in parentheses

Medicine and the Law

Agenised Flour

A YEAR ago Sir Wilson Jameson's committee reported[1] that there was no evidence of harm to human beings from agenised flour, but it recommended that the 'Agene' process should be replaced by treatment with chlorine dioxide This recommendation was accepted by the Ministries of Food and Health and by the milling industry, but the industry has been unable so far to complete this substitution, and the testimony at a recent inquest suggests that the public may have continuing misgivings about our bread supply

The dead bodies of a husband and wife and their infant child were discovered in their home in Hull. The husband's body was hanging by a rope from the ceiling of the bathroom, the wife had been asphyxiated by a cord round her neck, and the child had died from drowning Dr Philip Science, police-surgeon, told the coroner that there were no signs of poisoning The jury found that the husband had murdered his wife and child and had then committed suicide.

Dr J J Coghlan said that the deceased husband had complained to him of palpitation, pain over the heart, inability to sleep, and a feeling that he was losing his mental grip Dr Coghlan associated these symptoms with the consumption of agenised flour The treatment of wheat or other cereals with nitrogen trichloride, he said, produced a poison which had not yet received a name, flour so treated had been banned in every country in the world except this. The death-rate from heart disease had risen by 40,000 per year since the flour was introduced "practically every person who comes to me is suffering from agenised poisoning", the bulk of the people in the country were feeling the effects of agenised flour, and 250,000 had already lost their lives from this cause since 1940 On the other hand, Dr H E Magee, senior medical officer (nutrition) at the Ministry of Health, emphasised to the coroner and jury that there was no evidence that agenised flour had any harmful effect on man Toxic effects were produced on dogs and ferrets, but not on rats or guineapigs or on man He explained that the object of treating flour with nitrogen trichloride was to give effects similar to those produced by simply storing the flour for some time, it resulted in a whiter and more palatable loaf.

The coroner, in summing up, placed the conflicting evidence before the jury, indicating his own opinion that the weight of evidence was against chronic poisoning by agenised flour He told the jurors that, if they agreed with that opinion, they could add a rider accordingly They seem to have refrained from pronouncing upon an issue which a coroner's jury is not ideally equipped to decide nineteen had 32 cases between them 16 being single cases, and 16 associated with others The association attempted another survey in 1947 and 1948, but again the information collected was incomplete In 1947 single paralytic cases occurred in at least seven boys' schools and five girls' schools in term time One of these incidents was described in detail by Ryle (1948), who considered that there was a widespread epidemic of indefinite illness and non-paralytic poliomyelitis affecting two houses There can be little doubt that in boarding schools the single paralytic case is very much more common than are multiple cases, but on the present information it is impossible to say how much more common

---

[1] See *Lancet* 1950 i 227 *Ibid* p. 219

MISCELLANEOUS OUTBREAKS

(1) *In a training ship* for 229 boys aged 13–16 the first case had onset on Jan 19, 1948, and the second on Feb 3 The boys had returned from Christmas leave on Jan 6, and there had been a very extensive outbreak (at least 35 cases) of pharyngitis among them before Jan 19 This went on, and subsequently *Strep hæmolyticus* type 18 was isolated from many cases The community was an unusually closed one, because the boys went ashore only in parties on Sundays They slept in hammocks on very extensive decks Some of the staff lived ashore

(2) *In a concentration camp* in Holland in August–December, 1943 (Speijer 1946), there were 58 cases, 31 being paralytic with recovery and 3 fatal in a total population of about 9000 1 single case occurred in July, 1 in August, 4 in September, 12 in October, 37 in November, and 3 in December There had been an epidemic in Amsterdam in July–October, 1943 (Van der Wey 1945) The curve of incidence resembled that of the Broadstairs outbreak, except that it was spread over a much longer period

(3) *In a troopship* returning from the East in 1947 with 4000 troops 2 cases occurred in soldiers with dates of onset Sept 5 and Sept 14, and a third in an officer with date of onset Sept 16 The voyage lasted from Sept 1 to Sept 29, and there was a good deal of minor illness on the voyage, with a peak of incidence at the time of onset of the first paralytic case So far as is known, there were no secondary cases in the communities to which the passengers dispersed on arrival in this country

(4) *In an orthopædic hospital* the first case, with date of onset July 9, 1949, was transferred from a hospital for infectious diseases to the orthopædic hospital on Aug 31, twenty two days after onset Case 2 (date of onset July 19) was transferred on Aug 18 (thirty days after onset) Case 3 was in a child, aged 5 years, who had been in the orthopædic hospital for many months with a tuberculous hip The date of onset was Aug 30, twenty eight days after the admission of case 1 and twelve days after the admission of case 2 Case 4 was in another child in the ward, and the date of onset was Sept 16, forty five days after the admission of case 1 and twenty nine days after the admission of case 2 Both case 3 and case 4 played particularly with case 2 This is the incident to which reference was made earlier in the discussion of length of infectivity (see also fig 5, no 19) There was a high incidence of poliomyelitis in the neighbouring city at the time, and possibly the virus was introduced into the ward by some person other than case 1 or case 2 In view of the usual teaching about the short period of infectivity and the rarity of cross infections, however, this incident is disquieting and seems to justify a close lookout for, and the accurate recording of, similar incidents in other hospitals

DISCUSSION

The outbreaks described here have varied greatly in duration, seasonal incidence, and severity, and it is difficult to trace any clear relationships between these features and the type of community involved The following tentative generalisations are perhaps justified

Camp outbreaks seem to have a high attack rate of paralytic cases, and the virus seems to be confined, at first, to a fairly restricted group, though it is quickly and widely disseminated within that group

In the outbreaks in children's homes an unexpected feature has been the relatively high attack rate in the staff In view of the fact that attack rates in the general population are considerably higher in children than in adults it is surprising to find outbreaks like those in the two homes near London (fig 2) It is not clear whether this has something to do with susceptibility or whether the conditions for the spread of infection were particularly favourable in one section of the community

In schools there seems to be no way of prophesying what is likely to happen when a paralytic case occurs Short sharp outbreaks and long drawn out ones have occurred both in small homogeneous communities of the preparatory school type and in more complex communities of the public-school type There is perhaps a little evidence that in the public school one house tends to be affected first, and that, as in the camp outbreaks, the virus may at first be confined to a fairly narrow circle, though widely distributed within that circle The difficulty is that, if none of the early cases is paralytic, dissemination of the virus may be a silent process, and the first sign of an outbreak may be the occurrence of paralytic cases in different houses In the accounts of outbreaks there are many instances of a boy having a mild indefinite illness, returning to school for perhaps a week, and then developing paralysis This is the well known "dromedary" type of onset, and it is likely that in the stage of remission the patient may disseminate virus widely It has been noted that the occurrence of multiple paralytic cases seems to be very uncommon in schools for girls, and it is possible that this relative immunity may be associated with the fact that girls are usually kept in bed in isolation for more trivial illnesses than are boys (Medical Research Council 1938) The problem is, however, full of difficulties, because the occasions when indefinite minor illnesses are really a harbinger of poliomyelitis must be very rare compared with the occasions when they are not There seems to be no satisfactory solution until some practicable way of detecting non paralytic cases is discovered

Outbreaks are undoubtedly most common in the autumn term, less common in the summer term, and very uncommon in the Lent term, but there seems to be no particular stage of term at which an outbreak is likely to occur It is, however, difficult to be sure of this, because the true beginning of an outbreak may be, and probably usually is, a silent process

Instances have been found of apparent prolongation of the period of infectivity of the disease beyond that usually regarded as the danger period These have been few and necessarily uncertain, but it seems desirable that in future a careful record should be made of such occurrences It is worthy of note that in all the outbreaks studied there has not been a single instance of a definite paralytic case in a kitchen worker

It must be admitted that the accurate study of outbreaks of poliomyelitis is difficult and somewhat discouraging Even when elaborate facilities for examination of specimens for virus are available, it is necessary to select certain cases for examination and to make deductions which may or may not be true about what is happening in the community as a whole The discovery of the viruses of the Coxsackie group (Dalldorf and Sickles 1948, Curnen et al 1949), which are easier to work with than the virus of poliomyelitis, offers hope that in future it may be possible to get more help from the laboratory in the epidemiological investigation of some outbreaks of a similar type of disease in semi closed

Letters to the Editor

INFECTION OF "CLEAN" SURGICAL WOUNDS

SIR,—The excellent article (March 17) by the late Mr Girdlestone and his colleagues states that "no good purpose is served by pasting fabric on the skin with mastic before making an incision the mastic is one more material to sterilise and keep sterile" Admittedly, the convenient practice of making an incision through stockinet pasted on with 'Mastisol' has many defects The stockinet is not waterproof, it is in fact freely porous, and if it becomes wet by perspiration or blood it should form a continuous medium for the passage of organisms from the skin to its surface Furthermore, the skin edges are exposed when the incision is made and they remain exposed during the operation But the practice has something to recommend it and, faute de mieux, it may I suggest, be accepted

In the first place, the mastisol is not one more material to sterilise, but is in fact antiseptic and when it has set it forms a barrier between the skin and the surface of the stockinet If the stockinet remains dry, as in moderately short operations under tourniquet, the stockinet and mastisol form a barrier and lessen the chances of contact of hands, needles, ligatures, and sutures with skin, even though, because the skin edges are exposed, the barrier is only partial One should remain mindful of this defect

Skin towels are certainly no better as they are not waterproof and the method of fixing them damages the skin edges and may make holes in the towels themselves Instead of stockinet I have used oil silk, sterile waterproof strapping without the adhesive, and 'Nylon' film in an effort to find a waterproof cover that could be used as stockinet is used but these materials do not adhere to and fit, the contours of the operation area as well as the stockinet and they are more likely to come unstuck during operation

With regard to the general draping of the operation field, as distinct from the immediate vicinity of the wound, it is surprising how varied is the insistence among different surgeons on waterproof draping Yet the practice of using towels without sterile mackintoshes under them over an area which becomes damp with blood and skin exudation cannot be justified as effective for if the towel becomes damp there is a continuous medium between the skin and the surface of the towel.

Reference is made in the article to the storage of nylon in 1-60 phenol Though nylon is unharmed by any of the usual sterilising agents phenol is an exception, after a day in 1-60 phenol nylon breaks easily

Scunthorpe Lincolnshire **DAVID F THOMAS**

SIR,—The article by the late Mr Girdlestone and his colleagues recalled to my mind that I had been associated with a series of "clean" surgical cases which became infected

This occurred during the earlier part of last year Since I was concerned with all the cases either as surgeon or assistant I felt sure that I was to blame The wounds all became infected with a penicillin resistant strain of *Staphylococcus aureus* I had my throat swabbed and cultured, with negative results but my hands persistently grew a similar strain My wife at this time was having a recurrence of an old osteomyelitis, and cultures of the discharge grew a similar resistant staphylococcus I was becoming increasingly depressed by the prospects of having to give up surgery when one of my chiefs told me of a method of ridding oneself of this plague

The method is that after the usual 'scrubbing up" the hands are dried and the tips of the fingers dipped into a 1% solution of iodine in 70% spirit and the gloves put on Unless one is doing a series of short cases this treatment does not stain the fingers It is, however, rather hard on skin, and after a fortnight of this I found that the skin was beginning to desquamate The swabs taken from my hands no longer grew any *Staph aureus* and no more wounds have gone septic I therefore stopped the treatment, and since then have had no cause to return to it I was most grateful to the surgeon who suggested the course to me, and feel that his advice may prove useful to others

Norfolk and Norwich Hospital **N K CONNOLLY**

SIR—Does a surgical mask really retain all infective particles? A little work in a coal cellar has seemed to me to throw doubt on this

Wearing a surgical mask I riddled some slack in my coal cellar By the time the work was finished there was a haze of coal dust, and on emerging from the cellar I found that the mask round the area covering my nostrils was much smudged and on taking off the mask that my nostrils, my moustache in front of the nostrils, my nasal passages, and the mucus from the back of my pharynx were black with coal dust

If coal dust particles are not held back, can one expect the very much smaller microbic particles to be retained?

MUNCHAUSEN'S SYNDROME

SIR,—Between two admissions to the Queen Elizabeth Hospital, 26 hospitals (including Dr Short's) seem to have lodged the resourceful guest described by Dr Short (March 17) Both admissions here were on account of blood in the urine, the second was after his return from France in August, 1950 Our travel stained file on this patient is at the moment with us

Queen Elizabeth Hospital
Birmingham **G H ARMITAGE**

SIR,—I was interested to read of Dr Short's patient, This man was admitted to Chester City Hospital in September 1950, having collapsed at Crewe Station

He again complained of renal colic type of pain and hæmaturia He developed bleeding from the ears and nose while in the ward He had acute stomatitis which he was reluctant to have treated and he would not allow anyone to catheterise him He discharged himself and was intending to go to Glasgow If he reached his destination he has apparently not attended the Western Infirmary again.

Another patient is a man, aged about 35, claiming to be an ex Commando

He presents as an acute abdominal emergency—usually a leaking perforated ulcer He claims to have been operated on in Carlisle and Inverness I first saw him at Liverpool Royal Infirmary in February 1950 where he was admitted After several days observation it was decided to excise a persistent sinus from a lower midline wound The patient was transferred to a convalescent home shortly after operation and readmitted to Liverpool Royal Infirmary about a week later as he was thought to have renal colic After two days treatment on fluids only the patient was discharged About the beginning of April, 1950 the patient was admitted to this hospital with a diagnosis of leaking perforation I was then a house physician here, and saw the patient being admitted He must have recognised me as he discharged himself an hour or two later before I had the opportunity to confront him

Royal Infirmary Chester **ROSEMARY J BOLAM**

SIR—The patient described by Dr Short was admitted to this hospital on Feb 19, 1951

He had been found collapsed in the street with bleeding from the ears On apparently recovering consciousness he complained of severe griping pain in the lower abdomen and gave a history of hæmaturia for two days In the course of the next few days he refused investigation and treatment, and he told a story of having had purpura

MARCH SURGERY

When bicycles stand by the wall
And Mr Shepherd shows his nail
(Ingrowing toe-) and Mrs Small
Wants pills because she's feeling pale,
When cheek to cheek and jowl by jowl
The patients sit in rows and growl
" Me next, not you "—a merry note,
While Mr Jones describes his throat

When all around the rain doth pour
And coughing drowns the frequent plaint,
When gas is cut and what is more
The electric light is dim and faint,
With piles thrombosed and feeling foul
Small wonder that they sit and growl
" Me next not you "—a merry note
While Mr Jones describes his throat

* * *

In the war years we got used to things coming through the roof, they were part of the game Some were even more or less welcome—the rattle of our own flak on the rooftops, for instance—but some went too far, as when in Normandy some benevolent Teutons holidaying on the outskirts of Ranville persisted in knocking holes in the roof of my R A P Still, as I say, we got used to these things, so that by the time we took part in the airborne landings around Hamminkeln, on the far bank of the Rhine, we were fully prepared for the pannier of blankets which came through the tiled roof of the farmhouse in which the dressing station had been established The R A F supply drop was right on the target area, and the blankets were badly needed

After five years of so called peace one no longer expects things to come through the roof I was therefore unprepared for the incident of the other day I was down in a provincial cathedral town examining new entrants to the railway service All was going quietly I remember hearing footsteps overhead, which surprised me, for I had always understood that my room was on the top floor, but I did not stop to wonder what room actually was up there Anyway, footsteps they certainly were, and for a time there was a fair amount of coming and going overhead Suddenly there was a loud explosive noise followed by a tearing sound, whereupon the room was filled with thick clouds of dust and large pieces of plaster were strewn all over the place When the air cleared a little all that could be seen was one large black booted foot protruding through a hole in the ceiling It was an extraordinary sight, unique in the annals of our department We are used to looking at feet, but not with the boots on, and, like the house of Saxone, we examine *both* feet

For once in my life I managed to say the appropriate thing on the spur of the moment "That," I declared in a cool level voice, " is what the obstetricians call a foot presentation " But alas, my lay audience comprehended it not, and my words fell on heedless ears Apart from my brilliant but futile effort nobody said a word, the suddenness of the event stilled every tongue and above our heads silence reigned Strangely enough, there was not even a muffled voice, and more strangely still not even a muffled curse, to be heard—only the sound of falling plaster as the great booted foot waggled to and fro in an attempt to extricate itself from our ceiling Finally, scattering a parting shower of plaster and laths for good measure it disappeared into the heights of the roof, leaving a gaping ugly hole in the ceiling, an obvious exit wound with ragged everted edges

As we swept the plaster aside I noticed that the largest pieces were grouped in neat clusters round the chair from which I had risen a few seconds before the Black Foot appeared A few minutes later a startled sweep appeared and tendered his apologies While clearing soot from a chimney overhead he had missed the plank laid across the joists and had trodden heavily on the plaster My chief clerk remarked ' I've often had money on a horse, but that's the nearest I've been to getting anything from a sweep " But the highest mark went to Albert, our porter handyman, who came to tidy up the mess " And to think," said Albert, " that I recommended him "

* * *

I had a rewarding experience a week or two ago One of the men in my St John first aid class shook me vigorously by the hand and thanked me deeply for saving his wife's life I suppose I looked puzzled, for his wife was not a patient of mine, so he explained " You did it by proxy, doctor," he said, " and I was the proxy Last Saturday morning, when I was at home, she was suddenly struck down with acute pain " He described her signs and symptoms with an astonishing amount of clinical detail, and went on " I phoned our doctor but he was out on his rounds I remembered what you told us and decided she probably had either an internal hæmorrhage or an acute abdomen So I got on to the hospital, not saying who I was, and told them to get the theatre ready at once for an acute abdomen I rang off before they could ask too many questions, so I hoped they would think I was a real doctor Then my neighbour got out his car and we rushed the wife along They operated straight away and the house surgeon told me afterwards that she had a ruptured ectopic and bringing her in quickly undoubtedly saved her life "

One does not often get such dramatic evidence of the value of first aid lectures in peace-time During the war their importance was more obvious It seems a little giving up an evening every week to this job in general practice—you must expect to be called away in the middle of a lecture now and then—but the classes are so keen that you soon find yourself looking forward to the lectures

The main thing is to tell plenty of clinical stories be dramatic, and wring all you can out of your cases Don't just go over the book with the class—they can read the St John textbook for themselves, and it is very clearly written In the practical classes I always tell the victims who are being bandaged or splinted to imagine they are in Hollywood and put on a really convincing act as an injured person When they are having a fracture of the forearm put up, for example, they must not stick out their arm to make it easy to bandage If they can groan a bit and look alarmingly ill, so much the better Every first aid class loves a good drama

* * *

" NO CONSULTING HOURS
' IF YOU HAVE FLU TAKE 2 ASPIRINS AND GO TO BED

So read the notice posted on the plate over the usual " 9–10, 6–7, except Thursdays " Is this a pointer to the future by a man ahead of his time ? If, as many contend, there is no real need to see your patients at all, and they can be treated just as well by rule of thumb, why should the G P go traipsing round the houses—upstairs, downstairs, and in the patient s chamber ?

Slot-machine medicine may be just round the corner The *Mechanical G P* will have to be more complicated than those that used to sell you a bar of chocolate, milk or cream, or stamp out your name on a zinc strip—remember ? I visualise a row of buttons, like a cash-register, with a symptom or sign printed over each When you press *Headache*," *Tired in the Morning*, " *Too many Cocktails*," and ' *Whites of the Eyes Yellow* ' there'll be a whirring noise and—Bob's your uncle!—out will come Form E C 10 bearing your (signed) prescription, a certificate for sickness benefit, a card of instructions on diet and general behaviour and a slip in triplicate stating your weight, height and diagnosis and your fortune—one for the Executive Council, one for the M O H, and a third for you as a souvenir

There will be an ingenious protective device for the Saturday night joker who tries to wreck the Auto doctor ' by pressing *Frequency of Micturition* and *Can't Pass my Water* " at the same time I mustn't reveal the details of this, but no joker will need a second lesson Every doctor starting in practice will receive a new machine with screws for fixing *it to the front gate*, in lieu of basic salary

But perhaps it won't be like this at all and consultations will be " By Television Only " Who knows

Children's orthopædics is becoming a staple industry

Letters to the Editor

INFECTION OF "CLEAN" SURGICAL WOUNDS

SIR,—The excellent article (March 17) by the late Mr Girdlestone and his colleagues states that "no good purpose is served by pasting fabric on the skin with mastic before making an incision . . . the mastic is one more material to sterilise and keep sterile." Admittedly, the convenient practice of making an incision through stockinet pasted on with 'Mastisol' has many defects. The stockinet is not waterproof, it is in fact freely porous, and if it becomes wet by perspiration or blood it should form a continuous medium for the passage of organisms from the skin to its surface. Furthermore, the skin edges are exposed when the incision is made and they remain exposed during the operation. But the practice has something to recommend it and *faute de mieux* it may, I suggest, be accepted.

In the first place, the mastisol is not one more material to sterilise, but is in fact antiseptic, and when it has set it forms a barrier between the skin and the surface of the stockinet. If the stockinet remains dry, as in moderately short operations under tourniquet, the stockinet and mastisol form a barrier and lessen the chances of contact of hands, needles, ligatures, and sutures with skin, even though, because the skin edges are exposed, the barrier is only partial. One should remain mindful of this defect.

Skin towels are certainly no better as they are not waterproof and the method of fixing them damages the skin edges and may make holes in the towels themselves. Instead of stockinet I have used oil silk, sterile waterproof strapping without the adhesive, and 'Nylon' film in an effort to find a waterproof cover that could be used as stockinet is used, but these materials do not adhere to, and fit, the contours of the operation area as well as the stockinet and they are more likely to come unstuck during operation.

With regard to the general draping of the operation field, as distinct from the immediate vicinity of the wound, it is surprising how varied is the insistence among different surgeons on waterproof draping. Yet the practice of using towels without sterile mackintoshes under them over an area which becomes damp with blood and skin exudation cannot be justified as effective, for if the towel becomes damp there is a continuous medium between the skin and the surface of the towel.

Reference is made in the article to the storage of nylon in 1–60 phenol. Though nylon is unharmed by any of the usual sterilising agents, phenol is an exception; after a day in 1–60 phenol nylon breaks easily.

Scunthorpe, Lincolnshire. DAVID F. THOMAS.

SIR,—The article by the late Mr Girdlestone and his colleagues recalled to my mind that I had been associated with a series of "clean" surgical cases which became infected.

This occurred during the earlier part of last year. Since I was concerned with all the cases either as surgeon or assistant I felt sure that I was to blame. The wounds all became infected with a penicillin-resistant strain of *Staphylococcus aureus*. I had my throat swabbed and cultured with negative results, but my hands persistently grew a similar strain. My wife at this time was having a recurrence of an old osteomyelitis, and cultures of the discharge grew a similar resistant staphylococcus. I was becoming increasingly depressed by the prospects of having to give up surgery when one of my chiefs told me of a method of ridding oneself of this plague.

The method is that after the usual "scrubbing up" the hands are dried and the tips of the fingers dipped into a 1% solution of iodine in 70% spirit and the gloves put on. Unless one is doing a series of short cases this treatment does not stain the fingers. It is, however, rather hard on skin, and after a fortnight of this I found that the skin was beginning to desquamate. The swabs taken from my hands no longer grew any *Staph. aureus* and no more wounds have gone septic. I therefore stopped the treatment and since then have had no cause to return to it. I was most grateful to the surgeon who suggested the course to me, and feel that his advice may prove useful to others.

Norfolk and Norwich Hospital. N. K. CONNOLLY.

SIR,—Does a surgical mask really retain all infective particles? A little work in a coal cellar has seemed to me to throw doubt on this.

Wearing a surgical mask I riddled some slack in my coal cellar. By the time the work was finished there was a haze of coal dust, and on emerging from the cellar I found that the mask round the area covering my nostrils was much smudged, and on taking off the mask that my nostrils, my moustache in front of the nostrils, my nasal passages, and the mucus from the back of my pharynx were black with coal dust.

If coal-dust particles are not held back, can one expect the very much smaller microbic particles to be retained?

Eastbourne. T. HUNTER.

MUNCHAUSEN'S SYNDROME

SIR,—Between two admissions to the Queen Elizabeth Hospital, 26 hospitals (including Dr Short's) seem to have lodged the resourceful guest described by Dr Short (March 17). Both admissions here were on account of blood in the urine; the second was after his return from France in August, 1950. Our travel-stained file on this patient is at the moment with us.

Queen Elizabeth Hospital,
Birmingham. G. H. ARMITAGE.

SIR,—I was interested to read of Dr Short's patient. This man was admitted to Chester City Hospital in September, 1950, having collapsed at Crewe Station.

He again complained of renal-colic type of pain, and hæmaturia. He developed bleeding from the ears and nose while in the ward. He had acute stomatitis which he was reluctant to have treated, and he would not allow anyone to catheterise him. He discharged himself and was intending to go to Glasgow. If he reached his destination he has apparently not attended the Western Infirmary again.

Another patient is a man, aged about 35, claiming to be an ex-Commando.

He presents as an acute abdominal emergency—usually a leaking perforated ulcer. He claims to have been operated on in Carlisle and Inverness. I first saw him at Liverpool Royal Infirmary in February, 1950, where he was admitted. After several days' observation it was decided to excise a persistent sinus from a lower midline wound. The patient was transferred to a convalescent home shortly after operation, and readmitted to Liverpool Royal Infirmary about a week later as he was thought to have renal colic. After two days' treatment on fluids only the patient was discharged. About the beginning of April, 1950, the patient was admitted to this hospital with a diagnosis of leaking perforation. I was then a house-physician here, and saw the patient being admitted. He must have recognised me as he discharged himself an hour or two later, before I had the opportunity to confront him.

Royal Infirmary, Chester. ROSEMARY J. BOLAM.

SIR,—The patient described by Dr Short was admitted to this hospital on Feb. 19, 1951.

He had been found collapsed in the street with bleeding from the ears. On apparently recovering consciousness he complained of severe griping pain in the lower abdomen and gave a history of hæmaturia for two days. In the course of the next few days he refused investigation and treatment and he told a story of having had purpura

Telegrams to hospitals in Ireland which he mentioned revealed that at one of them, in 1947, he had been admitted under similar circumstances and discharged as a mental defective with self inflicted wounds They had apparently discovered that he added blood from his ears to the urine after it was passed He discharged himself, refusing to have treatment or to be cystoscoped

I warned other hospitals in the district, and I found that just before he came to Ramsgate he had been discharged from another hospital in Kent

General Hospital, Ramsgate P J COOK

SIR,—The patient described by Dr Short has undoubtedly been our guest recently

He was admitted on March 1, 1951, apparently bleeding from both ears, the nose, and the urinary tract, and he was complaining of pain resembling renal colic He told us, among other things, that he had been in hospital in Paris and at Maidstone After a few hours we suspected that he was malingering, but it was difficult to explain away a considerable amount of blood in the urine His locker and clothing were searched, but only a safety pin was found It seemed fairly certain that he transferred blood from his nose into the urine bottle while lying curled up in bed under the clothes with screens around him This he persisted in doing from time to time, and he would not allow the screens to be removed He gave evidence of some medical knowledge and incidentally helped to make his own bed very efficiently ! A suggested cystoscopy led to his demand for discharge The police were informed and took a statement, and then, signing a certificate to say that he was going out on his own responsibility, he left the hospital four days after admission

Lister Hospital
Hitchin, Hertfordshire A GREVILLE YOUNG

SIR,—I should like to report on one more case of Munchausen's syndrome I have now known the patient personally for nearly seven years The fact that he has a tuberculous chest lesion has enabled us to keep to some extent a record of his odyssey through the various hospitals I am, however, convinced that this record is far from complete

All who have dealt with him will no doubt remember him if we call him Robinson Crusoe He is single, 38 years old His occupation is given as capstan operator, kitchen help in a holiday camp, painter and decorator, or more often as lorry driver, but he never works

He was first referred to our chest clinic in 1940, after a presumably quiescent tuberculous lesion at the left apex had been found at Brompton Hospital He then gave a history of having collapsed in the street with chest pain on three occasions in 1935, and of having been admitted to local hospitals for short periods He attended the clinic very erratically

In March, 1947, he attended the Middlesex Hospital as an outpatient, complaining of symptoms suggestive of colitis He was admitted no cause for his complaints was found, and he landed eventually in the psychiatric department The psychiatrist gave the opinion that the patient was a pathological liar and a psychopath on whom any form of psychological treatment was wasted He was discharged in May, 1947

In August, 1947, he collapsed in the street with "stomach pain," and was admitted to Ashford Hospital He was discharged from there after three weeks but was advised to attend again at the chest clinic His left apical lesion had broken down The radiograph showed a cavity, and his sputum was positive He was most uncoöperative regarding treatment, but eventually we persuaded him to have a left phrenic crush as an outpatient in January 1948

In October, 1948, he presented himself at St George's Hospital with bloodstained underwear, giving a history of hæmaturia after having been kicked in the stomach and perineum in a street fight From this time he has kept to this kind of history with minor variations

In January, 1949, he was again admitted to Ashford Hospital with a history of hæmaturia after injury to the abdomen and lumbar region He was soon discharged and referred to the chest clinic His chest lesion had apparently become quiescent Tomograms showed no evidence of cavitation, and repeated sputum investigations were negative

In May, 1950, he was brought by car to Hill End Hospital, St Albans, complaining of hæmaturia after injury to the left lumbar region sustained whilst cranking a lorry

In June, 1950, he obtained admission to the Central Middlesex Hospital stating that he had brought up a mouthful of blood and passed blood with his urine after being hit by the door of a lorry

His latest exploit brought him into the Prince of Wales Hospital, Tottenham in January, 1951, again with a history of hæmaturia and hæmoptysis after a lorry accident He described himself as a lorry driver, and stated that he had received chest injuries during the war and had been a prisoner of war He first gave an address in Glasgow In view of his chest lesion, arrangements were made to have him transferred to the chest unit of a large general hospital in our clinic area He was most anxious not to be sent there, giving as the reason that we had ' killed all his family there " However he was persuaded to let himself be transferred, but asked to be discharged during my first ward round after his admission

I have no doubt that he will sooner or later reappear in other hospitals

Chest Clinic
Hounslow, Middlesex. R HELLER

INCOME-TAX ALLOWANCES

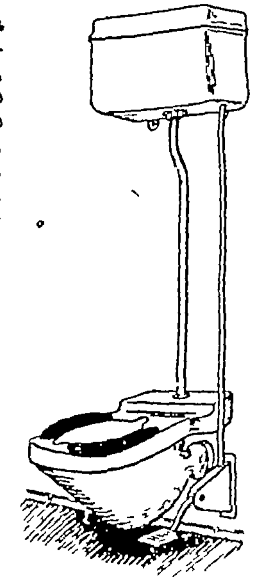
SIR,—Income tax allowances for subscriptions to journals and societies, and the purchase of textbooks, are awarded somewhat paradoxically General practitioners and part time specialists obtain this relief, in addition to numerous other benefits, from the Inland Revenue Full time employees of the N H S, mainly house officers and registrars, earning smaller salaries receive none of these allowances The Revenue authorities demand proof that the contracts of this group contain a clause requiring these subscriptions as a condition of employment This clause is not included in the usual contracts, and reasoning with the Inland Revenue is useless since they are allowed no scope for remedying such quirks

London, W 1 E M M BESTERMAN

PERSONAL HYGIENE AND SPREAD OF DISEASE

SIR,—I would like to endorse the views expressed by Dr Bourne (Jan 27) in relation to the spread of disease via closet impedimenta, and the lack of personal hygiene.

Foot operated lavatories have been in use in hospitals for many years and are a standard fitting of many sanitary fitting manufacturers Dr Bourne's adaptation of a hand pull closet to a foot-operated pattern is, however, open to criticism because wooden pedals, hinged to the floor, are used Firstly, wood, being an absorbent material, is liable to retain bacteria and will even permit organisms to grow and multiply, secondly, lavatory floors should be kept free from all obstruction, to facilitate efficient cleaning To this end I would recommend to all food factories the "Corbel type" pan, fitted with inserted pads instead of a seat, and foot operated cisterns fixed with a "Corbel hinge" into the wall



The greatest menace in most food factories is the lack of supervision of workers' personal hygiene, and the unnecessary handling of products I would recommend that all food-handlers should wear white coats Pegs should be provided for the reception of these coats near a wash-hand basin with hot and cold taps outside the w c, and no operator should be permitted to enter the lavatory without first removing his white coat The hands should be thoroughly washed and the nails scrubbed before touching the white coat again There is a grave danger that the soilings of carriers may be collected on white coats in fair concentration and taken into the factory, and therefore these coats should be treated with great care and not allowed outside the precincts of the factory building I have seen workers from food factories using their white coats as part of their normal dress, wearing them at home, shopping in them, and at break-time sitting on the ground or playing football in them

I think Dr Bourne has performed a most useful service in reminding us of the foot-operated lavatory flush

W A Bullough

The Counties Public Health Laboratories
66 Victoria Street London S W 1

Sir,—Dr Bourne's admirable article (Jan 27) is a reminder of many unpleasant conditions He observes that the high seated European water closet is unsuitable for small children, and that in the primary schools the lavatories are apt to become very rapidly " a hygienist's nightmare " Without detracting in any way from the truth of what he says I would suggest that he consider seriously the merits of the Oriental (squatting) latrine It is easy for the newcomer to the tropics to condemn this utensil as insanitary, but it has no seat which can be fouled and it favours a more natural position for defæcation than the European type The small child could cope with it more readily, providing it avoided falling in, but the need for some degree of acrobatic skill is discouraging to the corpulent and the ancient

Similarly an unbiased comparison of the methods of anal cleansing deserves attention. The irritation of hæmorrhoids with dry sheets of paper admittedly defends the fingers to some extent, but the Oriental method of washing with plain water offers progressive dilution —perhaps to a point of bacteriological insignificance A method encountered occasionally in English country districts, where wads of cabbage leaves are suspended on a nail on the door of the earth closet, is cheap and soothing but presents some difficulty when cabbages are out of season

One mild criticism of the modifications to the water-closet suggested by Dr Bourne the two pedals on the floor offer great possibilities to small children and fractures of the lavatory pan might very well result from fibrillation of the seat I remember a practitioner returning from Germany in 1920 armed with a combined toilet roll holder and musical box After its installation his two small sons were evicted from the lavatory with some difficulty, leaving behind them a sea of paper The foot pedals could be almost as attractive

THEORY OF CEREBRAL LOCALISATION

Sir,—How splendidly Dr Jefferson allies himself to other neurological giants, such as Hughlings Jackson and Sherrington, in your issue of March 17 ! His work on the pyramidal tract of the ferret (an animal conspicuously successful as an absolute localiser) well suits him to do so

How unhappily therefore does he use as his own ideas to belabour us, some of the points Mr McKissock and I specially made in our paper of March 3 For example, we stated (para 3) that Jackson did not believe in absolute localisation We have no disrespect for techniques obviously for are not clinical examination, hemispherectomy, and thinking techniques to be learnt ? Also, we particularly cited Dr Walshe's arguments that the function of organs is positive, and not preventive.

A critic never appears at his best when he implies, despite his own complete silence on a subject, that he has known all about it for years If it is true, he should be ashamed at having kept so many of us deliberately in the dark If it is false, the least serious among us has no difficulty in detecting the peevish and unbecoming deception

The National Hospital,
Queen Square London W C 1

UNFAIR QUESTIONS

Sir,—If I may make so bold as to disagree with Sir John Conybeare, I do so only from my advantage of having sat the Finals much more recently than he

Sir John says (March 17) that he regards some questions asked in examinations as unfair I agree, but I think the example he selected—the surgical complications of typhoid—singularly inappropriate The majority of young doctors nowadays are required to join the Forces after qualifying, and they may be posted to countries where typhoid and other diseases seldom seen in this country are common I was posted to the Middle East, and it was not long before I was very sorry that I had not received more training in the prevention, diagnosis, and treatment of typhoid, malaria and dysentery and less in the identification of pathological curiosities, which is such a popular pursuit at teaching hospitals

If Sir John really thinks some questions are unfair or unusual, he should have been present at my Final examination

In my medicine oral I was asked to identify from a classical 100-year old collection of paintings a case of advanced generalised ichthyosis My clinical case was one of Boeck s sarcoid of lung, which I managed to diagnose correctly, to the astonishment of my examiners by virtue of having sneaked a preview of the radiologist s report which had been left by the patient s bed by mistake I have never seen a case of either of these conditions since qualifying but I have been concerned with many outbreaks of typhoid fever

In my surgery oral I was handed a number of instruments to identify Among these was something that looked very much like the starting handle of a car At my wits end to think of what the thing could be used for in clinical surgery, I blurted out It s a car s starting handle ' in order to gain some time " Quite right ' said my tormentor without the slightest display of emotion, an instrument, with which every doctor must be familiar ' Among other instruments which I was asked to identify at this extraordinary session was a dinner fork. On seeing my look of amazement when handed this commonplace tool the examiner gave me a lengthy account of an operation he had once performed in Darkest Africa and in which a dinner fork had been an invaluable aid

After this nerve shattering interview I was ushered into the ward for the clinical oral After examining a patient suffering from some unheard-of condition, I saw the venerable and aged examiner approach His first question without any preamble was Who was Sun Yat Sen ? " My mouth dropped agape in utter bewilderment at this astonishing question in a frantic effort to correlate it with the case I had just seen I glanced furtively at the patient to see whether I had perhaps missed the fact that he was a Chinaman. But he was not I could only turn to the examiner, who was patiently awaiting an answer, and say He was Chinese, Sir This reply appeared to satisfy him, but I was completely demoralised for the rest of the interview.

My final ordeal in this nightmare of preposterous questions was when I was handed a jam jar containing a piece of something obviously grossly distorted by disease The specimen was so small however, that it could have been anything from a parathyroid gland to a piece of a big toe Taking a shot in the dark I said it was a testicular tumour I was wrong It was, in fact a breast biopsy

I am sure that my experiences are not unique, and that many other doctors must have similar tales to tell. But I have learned my lesson when the time comes for me to sit my membership I shall make sure that I have given close and detailed study to the highlights of modern Chinese history This, at least, should ensure a pass

London N 4 ADAIR GIRBY

P S —In fairness to the examiner concerned I should perhaps explain how Sun Yat Sen came into the picture at all Apparently somebody who invented some surgical instrument or other, the name of which I have long since forgotten, had befriended the good doctor when he qualified as the first graduate of medicine at the University of Hong Kong in 1891 The examination cannot be said to have been a total loss as I did at least learn this much

SIR,—Sir John Conybeare (March 17) takes exception to the question recently set in a paper for a higher qualification "Discuss the diagnosis *in a young woman* presenting herself with the complaint of double vision"

Russell Brain [1] states that, in this country, in disseminated sclerosis, females outnumber males by about 3 2 As disseminated sclerosis often presents with diplopia, the examiner may have had this in mind when the question was set

J B HOLROYD
Medical Registrar

BREAST-FEEDING IN BRISTOL

SIR,—The survey by Dr Ross and Mr Herdan (March 17) is to be welcomed, but, while I agree that breast feeding is to be preferred for the majority of babies, I am not sure that this can be deduced from the histiogram depicting weight distribution at six months of age

We are not told the birth weight distribution in the two groups, which is surely an important factor in determining subsequent weight Any group of artificially fed babies must be weighted with babies of both low and high birth weight since these are more difficult to sustain at the breast The former are handicapped by some degree of weakness in suckling, and the latter more commonly need temporary or continued complementary feeds, the additional work involved being for many mothers a deterrent to breast feeding It seems reasonable to expect a greater variation in both birth and subsequent weights in the artificially fed group, and it would be extremely interesting to know if this is indeed the case

Stretford, Manchester J N DOBSON

MATERNITY AND THE ADMINISTRATOR

SIR,—Perhaps it is not realised what repercussions the policy of the London Local Medical Committee may have if their resolution is fully implemented

According to Dr Frank Gray,[2] secretary of this committee, its aim is to force a return to more domiciliary midwifery Many are agreed that given the right conditions there is much to be said in support of home delivery What are these conditions? They include sufficient housing accommodation, freedom from undue economic anxiety, and adequate domestic help From the purely obstetric angle what women in labour, in addition to a skilled midwife, should have immediately available are the full resources of a modern obstetric service, which should include a flying squad equipped to deal with the emergencies of labour An efficient service of this nature can only spring from a base hospital where problems affecting childbirth are constantly being examined

Dr Frank Gray says that "a considerable number of people would still be alive today if only beds could have been found for them in hospitals" It would be interesting to know the age of and the illness which killed these patients Few occupy a position of greater value to the community than the expectant mother, particularly if she already has a young family Merely to deny her a hospital bed whilst really satisfactory home conditions do not exist in many places, is to take away with both hands

There is still an appalling wastage of infant lives, which amounts to about 53,000 a year in England and Wales This figure includes stillbirths (21,000), neonatal (17,000), and infant deaths (15,000) Will these be reduced by the present trend of administrative policy? Medical and lay administrators, in view of the power now vested in them, need to consider deeply the consequences for the community as a whole of any policy they initiate

PILONIDAL SINUS IN A BARBER

SIR,—It seems worth while to record a fifth case of pilonidal sinus in a barber's hand Attention was drawn to this condition by Patey and Scarff,[1] who cited three examples, a further case was also recorded by Ewing

A married man, aged 40, who had been a barber for 25 years, attended the outpatient clinic at the Cardiff Royal Infirmary in August, 1950 He was seen by Mr A C Lysaght who has kindly given me permission to publish the case

The patient complained of a swelling of his right hand which had been present for 18 months About 6 years previously he had first begun to notice that hair clippings became fixed in the skin of the web between the index and middle fingers of his right hand These hairs would have to be removed by pulling them from a small punctum which had formed in this position 18 months before he was seen, he had become aware of a swelling "about the size of a pea" deep to the punctum. This used to vary in size, but at that time he was not aware of any discharge from the punctum 5 months previously he had had acute inflammation of the area surrounding the swelling, this had yielded to conservative treatment For the past 3–4 months the swelling had steadily increased, and for 3 weeks before his admission to hospital in September, 1950, there had been a constant discharge of watery fluid from the punctum The patient had tuberculosis of the left hip at the age of 3 years, and as a result he walked with a limp He was otherwise healthy

In the web between the 2nd and 3rd fingers of his right hand there was a dimpled opening exactly like that of the ordinary postanal pilonidal sinus Deep to this was a discrete, spherical, mobile swelling, about 1 cm in diameter, which was not tender A little glairy discharge from the punctum was noted The opening would admit the blunt end of a straight cutting needle, and this passed easily for 5–6 mm, the end of the needle then appeared to be lying in the centre of the swelling

The sinus and the attached "cyst" were excised intact, and the wound sutured Healing did not take place by first intention but was complete in about 3 weeks The wound has remained firmly healed during the 5 months since then On cutting the swelling with a scalpel after removal, it was found to be solid with a central channel leading from the sinus opening There were dozens of hair clippings a few millimetres in length scattered throughout the solid material, and many lying loose in the central channel Microscopically, the lesion was an inflammatory granuloma Sectioned hairs were present in every field Unfortunately, the block was cut in such a way that the lining of the sinus was not identified with certainty It was clear to the naked eye that the mouth of the sinus was lined with epithelium, but how far this extended is uncertain

This appears to be the fifth recorded case of a hair bearing sinus in a barber's hand It differs from the four previously reported only in that the sinus was in the web between the 2nd and 3rd fingers Three of the previous cases were between the 3rd and 4th fingers, and the fourth was between the 4th and 5th fingers

There is no reason to doubt that in this case the lesion was caused by trauma to the skin by hairs, followed by penetration of the subcutaneous tissue by hairs In my view, these cases provide valuable evidence in support of a plausible alternative hypothesis to the unsatisfactory explanation of postanal pilonidal sinus as a congenital disorder

D H JENKINS

Royal Infirmary Cardiff — Senior Surgical Registrar

WILL WE NEVER LEARN?

SIR,—I am grateful to Sir Heneage Ogilvie for emphasising, in his letter of March 3, the deductions to be drawn from my report (Jan 27) on the treatment of wounds in the Korean campaign As he says, the report was based upon the work of other surgeons It was not my intention to criticise their work I had no first hand experience of the difficulties they had to overcome At that time, U N Forces were penned into a small area around Pusan, and the degree of organisation was much less than it is now

It did seem important, however, to draw attention to mistakes in treatment which were being made War surgery is not a big branch of the surgical tree at the moment, but this may not always be the case I hoped that other surgeons might be taught to avoid making the same kind of mistakes

I was fully aware that there was nothing new in what I wrote As Mr Shepherd pointed out (March 17), the monograph by Professor Trueta on the treatment of war wounds gives the basic rules for this branch of surgery The disheartening thing is that these rules were discovered, or rather rediscovered, during the 1939–45 war, and it seems that the discovery may have to be made again It is also clear that antibiotic therapy can only be a valuable ancillary

With regard to Sir Heneage's mention of a "young naval surgeon," and of the secondary suture and skin grafting which I did on patients who were under my care for only 42 hours, I must point out (*a*) that he has made an assumption which is not as accurate as I should like, (*b*) that the wounds so treated had been properly managed in the first place, and that the patients concerned were in a base hospital within an hour of leaving this ship, so that, for all practical purposes, they were under continuous surgical supervision, and (*c*) that with a number of years of experience of the treatment of war wounds and the like, I feel I ought to be able to recognise by now a wound which may safely be closed

PERARTERIAL BLOOD-TRANSFUSION

SIR,—Mr Delorme's report (Feb 3) on his carefully controlled and convincing experiments with arterial perfusion of the liver of exsanguinated dogs, raises again a related question of practical importance It is now over ten years since Brigadier General S Seely first reported from the Walter Reed Hospital, Washington (where he is now chief of the surgical service), on the value of perarterial blood transfusion for patients in extremis from exsanguination

I have recently had the opportunity of hearing Brigadier General Seely discuss his experience of this method He reserves it for patients who are truly in extremis—that is, in the state of so called irreversible shock, when continued intravenous blood transfusion no longer produces a response or recordable blood pressure on the arterial side Some such patients, if then given a retrograde perarterial transfusion through any readily available peripheral artery such as the radial, show response and return of their blood pressure to readable levels They can by this means be rendered fit enough for surgical treatment to control a source of internal hæmorrhage Brigadier General Seely was quite clear that perarterial transfusions are best reserved for such cases of advanced or neglected internal hæmorrhage which have failed to respond to intravenous transfusion

The success of the method appears to depend upon Pascal's law, which states in effect that an increase in pressure in any part of a closed fluid system is transmitted unchanged to all parts of the fluid The arterial system is not a closed system, but is nearly enough so to act for a time as such If a bottle of blood is suspended 6 ft above the patient and connected to the arterial system by the radial artery, then the pressure at the point of the cannula is the equivalent of 120 mm Hg This pressure may be transmitted to all other parts of the arterial system, at least for a time The rate at which blood flows out of the transfusion bottle into the arterial system is an indication of the rate at which it is being lost at the site of the hæmorrhage Brigadier-General Seely believes that this fact may help in determining the relative priority for operation of two or more injured patients admitted in extremis The patient whose blood runs from the bottle most quickly into his artery is the one who is bleeding most rapidly and is most in need of surgery

Clearly the method is not without danger, especially to the viability of the hand It should be reserved for patients who have failed to respond to intravenous blood, when there are reasonable grounds to believe that a source of hæmorrhage controllable by surgery is the cause of their condition

Experience of this method at the Walter Reed Hospital is said to encourage the view that it may be possible to revise upward some of our conceptions of irreversibility, for a limited group of casualties Arterial trans fusion certainly deserves a careful investigation here

London W 1 — PATRICK CLARKSON

Parliament

QUESTION TIME

Admission to Hospital Refused

Mr SAMUEL STOREY asked the Minister of Health if he would now make his promised statement upon the circumstances preceding the death of Charles Walter, who was found dying outside a lonely hut in Urmston Meadows, to which he had been returned after being refused admission to Park Hospital, Davyhulme, because he was not sufficiently ill, and to a welfare hostel at Ancoats, because he was too ill to be admitted there —Mr H A MARQUAND replied Full inquiry has established that the failure in this case was due to an error of judgment in not admitting this man to hospital, and not to any lack of liaison between the health and welfare services I am satisfied that the regional hospital board concerned has taken the steps necessary to prevent any repetition of the occurrence

Mr STOREY Is the Minister aware that diagnosis in this case was made in the open air and in the ambulance? Will he see that such a thing does not happen again?—Mr MARQUAND I am glad to say that arrangements have been made to set aside special beds for this type of patient, and that instructions have been given that when they are to be admitted to hospital or sent to another hospital, accommodation must be certain to be there before the patient is sent away

Distribution of Doctors

In answer to questions Mr MARQUAND gave the following figures for the population and number of doctors resident in different areas

	Population	*Doctors*
Bath	77 040	40
Blackpool	149 600	65
Southend-on Sea	151 400	60
Salford	177,700	66
Oldham	119 500	43
Leicester	287 200	120
Eastbourne	58 040	38
Hastings	65 670	44
Sunderland	178,100	58
Southport	85 490	47
Leeds	509 400	238
Bournemouth	139 600	82
Brighton	157 600	65
Reading	115 470	64
Stoke-on Trent	275,700	94

Tuberculosis Benefits

Brigadier J G SMYTH asked the Minister of National Insurance what was the position of a general practitioner under the new Tuberculosis Benefits Scheme of March 1, 1951 —Dr EDITH SUMMERSKILL replied The new regulations, like the Industrial Injuries Act under which they are made, only apply to persons in insurable employment As general practitioners as such are not so employed the regulations will not apply to them

Supplies of Aureomycin

Sir THOMAS MOORE asked the Minister whether he was aware that there was a great shortage of 'Aureomycin' in this country to meet the requirements of the medical profession, and what steps he was taking to make good the deficiency —Mr MARQUAND replied A recent temporary shortage has now been overcome Deliveries of aureomycin in capsule form from the British factory are adequate to meet present needs

Dental Students

Sir HUGH LUCAS TOOTH asked the Minister what was the *annual intake of dental schools in the years 1946, 1947,* 1948, 1949, and 1950 respectively —Mr MARQUAND replied 641, 654, 662, 611, and 606 respectively Sir HUGH LUCAS TOOTH How long does the Minister think it will be before there is an adequate number of dentists in this country ?—Mr MARQUAND The recent decrease is explained by the fact that during the war there was a lowered intake and therefore in the first few years after the war it was possible to increase the entry It is now necessary to get a balance and the numbers have been slightly reduced I agree that the total intake is not satisfactory in the country as a whole

Cost of Supplementary Services

Sir HUGH LUCAS TOOTH asked the Minister of Health how the various fees included in the total amount of £43,048,000 which was payable to dentists during the financial year 1949–50 were divided between fees for extractions, provision of new dentures, dental examinations, and dental conservative treatment, respectively —Mr ARTHUR BLENKINSOP replied Full information in this detail is not available But, on the basis of a sample, it is estimated that the total cost may be divided as follows examinations 5%, extractions 6%, dentures 61%, conservative work 28%

Sir HUGH LUCAS TOOTH asked the Minister whether he would give details showing how the £22,725,000 payable during the financial year 1949–50 for the testing of sight and the supply of optical appliances was divided as between fees for sight testing, fees for dispensing optical appliances, and the cost of supplying optical appliances, respectively —Mr BLENKINSOP replied Fees for testing of sight accounted for £4,719,847 out of the total of £21,733,620 paid in the financial year 1949–50 Separate figures are not available for dispensing fees and cost of supplying appliances, the estimated apportionment is £8,800,000 and £8,200,000 respectively

Mortality Statistics

Replying to a question Mr MARQUAND stated that the average age at death in Great Britain in the years 1939 and 1945 was 59 and 60 respectively The provisional figure for 1949 was 64

X-ray Examination of Miners

In reply to a question Mr P J NOEL BAKER, Minister of Fuel and Power, stated that the National Joint Pneumoconiosis Committee recently *decided that an experimental* scheme for the periodic X ray examination of miners was required before any general plan could be drawn up The personnel, equipment and organisation of the experimental scheme were now under consideration In the meantime all miners who had been diagnosed as having pneumoconiosis, including many thousands who continued their work at the mines, were re-examined from time to time, 50,000 other miners had been examined by miniature radiography under the National Health Service

Dr CHARLES HILL Will the Minister consult the Minister of Health with a view to diverting some of the mass radiography facilities to this even more important work than that upon which it is normally engaged ? Mr NOEL BAKER The Ministry of Health are represented on the committee which deals with this matter There is some division of opinion among the experts on whether mass miniature radiography *does detect pneumoconiosis* in its early stages

Obituary

JOHN ALEXANDER NIXON

C M G, B A, M D Camb, F R C P

Dr J A Nixon, who died in Bristol on March 17 at the age of 76, was emeritus professor of medicine in the *University of Bristol* and consulting physician to the Bristol Royal Hospital and to Southmead Hospital

He was born in Edinburgh, the son of Robert Nixon, a freight broker of Bombay, and his mother was the daughter of a surgeon-major in the Madras Army He was educated at Hurstpierpoint, Caius College, Cambridge, and St Bartholomew's Hospital, where he formed a lifelong friendship with the late G E Gask His literary tastes developed early, and he was editor of the hospital journal, as well as president of the Abernethian Society He qualified in 1900, and after holding resident posts in London he went to Bristol in 1902 as senior resident officer at the Bristol Royal Infirmary Four years later he was elected to the staff as assistant physician, in 1908 he became full physician, and later professor of medicine in the University of Bristol He acted as dermatologist as well as physician at the Infirmary In 1911 he was elected F R C P

During the 1914–18 war with the rank of colonel he served in France, alongside his friend Gask, as medical consultant to the Fourth Army He was twice mentioned in despatches, and he was *appointed* C M G in 1919

Between the two wars he filled numerous and varied offices He was regional adviser to the Ministry of Health, a member of the Industrial Health *Board, county* director of the Bristol branch of the British Red Cross, and inspector of examinations for the General Medical Council, and he took an active interest in *Brentry* Institute, Stoke Park Colony, and Southmead Hospital. In its jubilee year he was president of the Bristol Medico-chirurgical Society, and it was characteristic of his wide interests that he chose as the subject of his presidential *address the Debt of Medicine to the Fine Arts* Members of a Hellenic cruise in 1939 will also remember his address on Greek athletics As Abernethian president he had *proved himself a ready speaker, and ease in* debate was the natural prelude to ease in journalism, and from 1926 to 1947 he was editor of the *Bristol Medico chirurgical Journal*

The port of Bristol stimulated his interest in naval medicine and the medical aspects of sea voyages His writings on these topics ranged from a *spirited defence* of Dr Dover against the charge of piracy *to his more* formal war-time FitzPatrick lectures to the Royal College of Physicians on Health and Sickness in the Merchant Navy He was early interested in nutritional disorders—he was one of the first workers in this country to use insulin—and with his wife he wrote a *Textbook of Nutrition* in 1938 In the thirties when *the shortage of domestic workers* in hospital was already beginning to be felt Nixon met the situation with sympathy and imagination Bristol ward maids were among the first in the country to become hospital orderlies, and a neat uniform and a badge further increased their self respect and prestige

When war broke out *in 1939*, although he was nearly 70 Nixon travelled up and down the country lecturing on civil defence and anti gas measures He was also regional adviser in medicine to the Emergency Medical Service

But medicine occupied only a part of his life He loved music—he had held *a choral exhibition at Cambridge*—and he was lately chairman of the Bristol Light Opera Company A zealous freemason he was past-master of St Vincent Lodge, and he held provincial grand lodge rank A friend after reading an obituary notice in a Bristol paper writes "It gives no inkling of the man himself, his bonhomie, and the good companion that he was. One never had a dull moment talking to John. It mentions his versatility but not his charm and his music and his pleasure in all things good and beautiful, which combined to make him the good friend he was to all of us. He was no self seeker nor trouble-maker, and it is true, and not mere platitude, to say that he leaves a gracious memory behind him."

He married Dr. Doreen Walker in 1924, and he leaves her with a son and daughter. A memorial service was held in Bristol Cathedral on March 21.

GEORGE HASWELL WILSON

M.D. Birm., M.B. Glasg.

Prof. Haswell Wilson, who died on Feb. 28, had held the chair of pathology in the University of Birmingham for over 25 years.

The son of a Scots doctor, he qualified in 1906 at Glasgow University, where he was Coates memorial scholar, John Reid prizeman, and Carnegie research fellow. He represented his university at three sports, captained its rugby XV, and in 1908 represented Great Britain in the high jump at the Olympic Games. Throughout his life he retained a keen interest in the athletic side of university life, and he was for many years a vice-president of the Birmingham University Athletic Club, and one of the judges—a post of which he was secretly proud—at its annual sports.

After qualification he went into general practice for a short time, but his appointment to a lectureship in pathology at the University of Glasgow under Sir Robert Muir, introduced him to the scientific and academic career for which his interests and talents peculiarly fitted him. During the 1914–18 war he was medical superintendent of the Western Infirmary, Glasgow. He was appointed to the chair at Birmingham in 1922, and he held it till he retired in 1949. He was also pathologist to the United Birmingham Hospitals.

As a morbid histologist he was in the front rank of his profession; and his wide knowledge and experience of both theory and practice, and the strong sense of duty and responsibility that he brought to his work, made his verdicts in the post-mortem room and the laboratory of great value to his clinical colleagues, his staff and his students. Possessed of a remarkable manual dexterity, his post-mortem technique was beautiful to watch in its accuracy, rapidity, and tidiness, and he took a justifiable pride in its performance. Such was the innate gentleness of his nature, however, that, while he never shrank from any professional duty in the post-mortem room, he always paid, and exacted from his colleagues, a due reverence for the dead. Some of the pathological investigations that he undertook for the coroner of the City of Birmingham were brilliant in their clear and simple solution of problems that appeared to be intricate and obscure, and it is much to be regretted that his disablement prevented him from preparing some of them for publication in his retirement. But though he published little in his own name, many of the publications by the members of his staff were the direct result of his encouragement. He was always willing and eager to help any member of his staff, not only in their academic and professional work, but also with their personal difficulties and private troubles and his advice was always valuable and his judgment sound.

In his professional work, however, he was happiest when he was teaching his students, or when he had gathered two or three members of his staff around him to expound some difficult matter in histological or microscopical technique, of which he was a master. His lectures, to the preparation of which he gave much time and care, and which he kept up to date by constant revision, were lucid in presentation and masterly in exposition. They were generally illustrated with some of the superb lantern slides that he made himself from the excellent photomicrographs he took on the apparatus that he built, 28 years ago from scrap material that he found in the department. His manual skill as a worker in wood and metal was outstanding, and the optical bench which he also built out of scrap materials is in constant use in the department today, and is still enabling workers to produce photomicrographs the equal of any produced by the other medical schools of this country. He had a remarkably efficient workshop splendidly equipped, in his own house, where he spent many happy hours of his leisure, devising and making things for the department or for members of his staff. I have a miniature optical bench, designed to take photomicrographs at magnifications of from 2 to 40 diameters, which he made for me—again out of scrap materials—and which will stand comparison with the product of any of the firms who manufacture microscopical equipment.

I could write much more about his love for children and his joy in the company of his own grandchildren; of his gentleness towards the sick in mind and body; of his love of nature and his wide and intimate knowledge of natural history; of his proficiency in fly-fishing; of his sure eye for a picture and his mastery of photographic technique; of his kindly and infectious humour; but it must suffice to say that he was the fortunate possessor of many talents, a connoisseur of several arts, and an able exponent of more than one science. Above all, he was a man of high principles, who was fearless in the discharge of what he considered to be his duty, but who respected the beliefs and honest opinions of others—a man who never attempted to dictate, and who scorned to evade. To me, who knew him so well, and who owe him so much, he has left an indelible memory of the gracious and kindly figure of one who, in success and in sorrow, in health and in the illness that marred the last three years of his life, fought always till, as Bunyan's character said: 'My sword did cleave to my hand; and when they were joined together, as if a sword grew out of my arm, and when the blood ran through my fingers, then I fought with most courage.'

J. F. D. S.

DAVID WHYTE

M.B. N.Z., F.R.C.S., F.R.A.C.S.

Mr. David Whyte, who died in Wellington on Dec. 29 at the age of 61, was the son of the Rev. Alexander Whyte, a pioneer of Presbyterian Church Schools in New Zealand. He graduated at Otago University in 1912, and after serving as a resident in Dunedin Hospital he came to England where he joined the R.A.M.C. in 1914, serving in France and on the North-west Frontier of India.

After demobilisation he took the F.R.C.S. in 1922, and held an appointment as house-surgeon at the Royal Cancer Hospital in London before he returned to New Zealand, to settle in practice as a surgeon in Wellington. For 25 years he was a member of the staff of the Wellington Hospital, becoming a senior surgeon in 1940. He also gave freely of his time to postgraduate teaching at the hospital, and to the cancer work of the Royal Australasian College of Surgeons, and for some years he was assistant editor of the *New Zealand Medical Journal*.

A colleague writes: "David Whyte was industrious and devoted to his practice and the welfare of his patients. Well up in surgical literature, he showed courage and insight in developing new fields, particularly in abdominal and œsophageal surgery. His charm of manner endeared him to patients, nurses, and colleagues, and everywhere he inspired great confidence."

RICHARD IRVINE POSTON

T.D., M.D. Belf.

Colonel Richard Poston, who died in Manchester on March 16 at the age of 54, was born in Belfast, and was a graduate of Queen's University; but all his professional life was spent in the Oldham district where he settled, at Failsworth, shortly after he qualified in 1922. From 1927 till 1938 he acted as surgeon to the Oldham Royal Infirmary and the Boundary Park Municipal Hospital.

During the first world war he served as a captain in the Royal Garrison Artillery, and he was wounded in Belgium in 1917. After qualifying he joined the Territorial Army and became battalion medical officer to the 9th Manchester Regiment, later transferring to the 125th Field Ambulance which in the second world war he commanded and took to France. After the evacuation at Dunkirk he took over the command of the 1st Casualty Clearing Station, and in 1942 he formed the 97th General Hospital which he took to North Africa. At the end of the North African campaign Colonel Poston commanded the 69th General Hospital in Italy He was invalided from the Army in October, 1944, because of a fractured leg On his retirement from active military service he became honorary colonel of the 7th (Western) General Hospital and of the 12th (Western) C C S.

For 27 years Poston played an active part in the affairs of the Order of St John of Jerusalem, of which he was an officer, and he served as a member of the the council for the County Palatine of Lancaster At the time of his death he was assistant commissioner (no 4 area), St John Ambulance Brigade, Manchester He was also a member of the Oldham and District hospital management committee and president of the local branch of the British Legion

His widow, Dr Margaret Poston, is an anæsthetist, and his son is a medical student at St Andrews University

Notes and News

HEALTH SERVICE ESTIMATES

The estimates of the cost of the National Health Service in 1951–52, published this week,[1] show a gross increase of £4,108,400 on the cost in 1950–51 for England, Wales, and Scotland the gross cost is put at £469,127,700, compared with £465,019,300 in 1950–51 Appropriations in aid during the coming financial year are estimated at £71,044,700, compared with £72,079,390 in the present year In England and Wales, the gross cost is expected to increase by £4,022,400 to £417,284,700 The cost of hospital, specialist, and ancillary services in England and Wales is expected to rise by £13,497,900 to £251,479,900 The principal reductions are in the general dental services, whose cost is expected to fall by £5,775,000 to £35,790,000, and in the supplementary ophthalmic services, whose cost is put at £17,560,000, compared with £25,665,000 in 1950–51 The estimate for general medical services—£42,900,000—is £166,000 higher than in the present year

COST OF ANTIBIOTICS

The expense involved when a new antibiotic is released for use in general practice is illustrated by the figures for chloramphenicol (' Chloromycetin ') In the seven weeks from its release on Dec 9, 1950, to Jan 31, 1951, the chloramphenicol dispensed by retail pharmacists for National Health Service patients amounted to £300,000, and dispensing, containers, &c, added a further £50,000, making a total of £350,000 The influenza epidemic was causing a big increase in prescriptions at this time, so the period cannot be considered a fair sample Nevertheless, for that period, the chloramphenicol prescribed in fact raised the average cost of all N H S prescriptions by about 2*d* The antibiotic is packed in vials of 12 capsules at a net cost of 50*s* a vial The average amount ordered on a prescription probably lies between two and three vials, so the average net cost per prescription is from £5 to £7 10*s* or, with the pharmacist's dispensing and other charges included, from nearly £6 to £8 15*s*

THE NEW STUDENT

We are so often told that we live in an age of hustle, where there is little time for old world courtesy, that it is a relief to find new customs being started with the kindly intention of putting people at their ease For instance, new patients today are often offered a helpful leaflet introducing them to their hospital Now Birmingham, in a booklet entitled *Introduction to a University*, has tried to give sixth forms some general ideas of what university education means and of the careers which are open to graduates Later sections describe undergraduate life at Birmingham, and give the qualifications required for admission and details of prospects in the different professions Competition for entry to the medical school is noted as exceptionally keen The annual intake of medical students is 100, and 25 of the places are reserved for women

The University of Edinburgh has adopted a different method of introduction, and last year for the first time held a conference for "freshers" during the weekend before the opening of the autumn term The conference, which was organised by the Students' Representative Council, included lectures on the history and administration of the university, conducted tours to the different departments, a concert, and a dance

A LIST OF SERIAL PUBLICATIONS

A *British Union Catalogue of Periodicals* has been proposed and is being compiled, but may take some time to complete Meanwhile the Harveian librarian of the Royal College of Physicians has thought it useful to prepare a list of the serial publications in the college library, and this is now available The term "periodical" has been interpreted literally, and the list contains such things as yearbooks as well as journals Since the college library specialises in the history of medicine, a relatively large proportion of the periodicals listed bear on this subject Belonging as they do to a reference library the periodicals are not available for loan except to other libraries, and for use by readers in the reference department, but 'Photostat copies of articles can be made

PROVISION FOR ILLNESS

MANY people still prefer to have private medical and nursing attention during serious illness, and it was for such people that the British United Provident Association—a non profit making organisation—was formed in 1947 By paying an annual subscription, which varies according to the benefits desired, members are assured of a grant towards medical and nursing expenses incurred by themselves or their dependents

Under the presidency of Lord Nuffield the association (61, Bartholomew Close London, E C 1) has become a financially sound and useful organisation, and in their annual report for the year ended last June the board of governors announce an increase in the number of new members

---

University of London

The following have been recognised as teachers in the faculty of medicine

Simon Behrman medicine J D M Cardell, R C Davenport C L Gimblett A G Leigh P McG Moffat, A Seymour Philps, F T Ridley, and Eugene Wolff ophthalmology all at the Institute of Ophthalmology, Chapple Gill-Carey, G H. Howells otorhinolaryngology Institute of Laryngology and Otology C P Blacker mental diseases, Institute of Psychiatry William Gunn medicine Royal Free J. N Hunt physiology Guy's R W Raven surgery J H. Wilkinson, pathology Westminster W W Sargant mental diseases St Thomas's R. W Wilson pathology St Mary's, O L C Sibley anæsthetics Royal Dental

University of Dublin

At a recent examination for the diploma in gynæcology and *obstetrics the following were sucessful*

F A Akerele L R Ashley, Wadie Amin Guindi Bishai, Russell Brown D C J Carter A J R Clarke Madanmohan Debnath J P M Droulers, W H D Fairbank Sami Waseef Ghali, Shaukat Haroon, Salah el Din Hussein Issa, Soosainathan Lourdenadin, P C McAuliffe M B Millerick G E Peters Aron Press Albert Schutz Anish Ranjan Sen Somasundrum Thuraiiretnam

Dr J H. Burn, F.R.S, professor of pharmacology in the University of Oxford, has been appointed John Mallet Purser lecturer for 1951 It is hoped that he will deliver the lecture in Trinity College, Dublin, on Wednesday, May 9 He is to speak on the Importance of Noradrenaline

University of Leeds

Dr M J Parsonage, who is assistant physician to the United Leeds Hospitals, has been appointed clinical lecturer in the department of neurology

The council of the university have recommended the institution of a part time course leading to the award of the diploma in public health.

Royal College of Physicians of Ireland

On March 16, the following, having passed the final examination of the Conjoint Board in Ireland, were admitted licentiates in medicine and midwifery

D B Barnett P B Carvill W F Clifford J L Davidson Emanuel Fischer J C Grogan P D McCarthy E S McDaniel Philip McGovern Dympna MacNamara Margaret M J O Dea Ignatius Ryan Dennis White

Royal Army Medical Corps Funds

The annual general meeting will be held at 11, Chandos Street, London, W 1, on Monday, April 9, at 5 P.M, when the following resolution will be considered

> That the administration of the Auxiliary Royal Army Medical Corps Funds be handed over to the Royal Army Medical Corps Fund to be administered in accordance with the Trust Deed of 1916 and objects of the 1939 Fund representation of the interests concerned being secured on the appropriate central committee.

National Coal Board

Dr John Rogan has been appointed chief medical officer in succession to Dr E H Capel, who has resigned

Dr Rogan who is 37 was born in Glasgow He graduated in medicine at Edinburgh University in 1935 and after holding junior hospital appointments was appointed tutor in clinical medicine at Edinburgh Royal Infirmary in 1937 In 1939 he took his M D During the war Dr Rogan served in the R.A.M.C, with the rank of lieut.-colonel as medical specialist to the Malaya Command and as officer in charge of the medical division of general hospitals in the Far East Later he was responsible for clinical research on malaria in the India Command After demobilisation he became senior medical officer with the Austin Motor Company then lecturer in industrial medicine at Glasgow University At present he is head of the environmental medicine section at the headquarters of the Medical Research Council. He became F.R.C.P.E. in 1947

Institute of Psychiatry

Dr Erik Essen Möller, professor of psychiatry in the University of Lund, will deliver two lectures at the Maudsley Hospital, Denmark Hill, London, S.E 5, at 2 P.M on Friday, April 6, and at 3 P.M on Monday, April 9 He will speak on Recent Swedish Studies in Mental Health

On Thursday, May 31 at 3 P M, at the Maudsley Hospital, Denmark Hill, London, S.E 5, Dr Jacques Le Beau is to lecture on Neurosurgical Difficulties in Performing Limited Prefrontal Operations

Birmingham and Midland Obstetrical and Gynæcological Society

The following office bearers have been elected president Prof J Chassar Moir, vice presidents, Mr H J Malkin and Mr S W Maslen-Jones, treasurer, Mr Samuel Davidson, secretary, Prof H C McLaren, members of council, Mr H. R Duval, Mr William Hawksworth, Mr L M Park, and Mr A. Wentworth Taylor

Army Dental Service

Colonel John Wren, B.D S late Royal Army Dental Corps, has been appointed director of the Army Dental Service in succession to the late Major General H J. Higgins

British Association

This year the annual meeting of the association will be held in Edinburgh from Aug 8 to 15 under the presidency of the Duke of Edinburgh

Congress of Catholic Doctors

The fifth International Congress of Catholic Doctors will be held in Paris from July 6 to 9 The offices of the congress are at 120, rue du Cherche-Midi, Paris, VI

Medical Art Society

On Monday, April 2, at 6 15 P.M, the society will hold their annual general meeting and dinner at Kettner's Restaurant, London, W 1 There will also be a private view of the annual exhibition at Walker's Galleries, New Bond Street, W 1 The exhibition will be open to the public from April 2 to 14

Transfer of a Hampshire Hospital

Queen Alexandra Hospital, Cosham, is to be transferred on April 1 from the Ministry of Pensions to the Ministry of Health, and will be incorporated in the Portsmouth Hospital Management Committee group This group already includes fifteen hospitals, and the committee also manages the Portsmouth and Isle of Wight Area Pathological Service No beds are closed because of lack of nursing staff

Higher Pay for Hospital Workers

The National Arbitration Tribunal have awarded increases in pay (8s a week for men and 6s a week for women) to domestic workers in hospitals and allied institutions and local authority residential establishments Porters, ward maids, orderlies, cleaners, and laundry and kitchen staff will all receive the increase About 120,000 whole time and 33 300 part time employees under the National Health Service, and 20,000 whole time and 5000 part time employees of local authorities, will be affected.

Salaries of Local-authority Dentists

The Dental Whitley Council (Local Authorities) have agreed on salaries and conditions of service for whole time dental officers employed by local authorities in Great Britain. These new scales, which are to operate from Oct 1, 1950, are as follows

Dental Officers—£500 per annum rising by annual increments of £50 to a maximum of £1250 per annum the employing authority having discretion to allow one increment for each year of experience in practice up to a maximum of five years

Chief Dental Officer—This range of salaries is governed by the population of the area served

Population not exceeding	*Salary Scales* (£)
100 000	1250 rising by one increment of 50 to a maximum of 1300
150 000	1250–50–1350
250 000	1250–50–1400
400 000	1250–50–1450
600 000	1250–50–1500
Over 600 000	At discretion

Ministry of Health

Sir Selwyn Selwyn Clarke has been appointed a principal medical officer of the Ministry He has lately retired from the governorship of the Seychelles, and during the late war he was director of medical services at Hong Kong

Position of the Doctor in Time of War

A meeting of members of the medical and legal professions is to be held to discuss this subject on Wednesday, April 25, at the Centre Universitaire Méditerranéen, Nice Further information may be had from the Institut d'Études Juridiques, Avenue Saint-Laurent, Nice, France

Faculty of Anæsthetists

Mr A D Marston has been re elected dean and Dr Frankis Evans vice dean of the faculty Mr Marston, Dr Ronald Woolmer, and Dr E W Rowbotham have been re elected to represent the fellows, and Dr S A Mason has been elected to represent the members, on the board of the faculty

Vellore Christian Medical College

A concert in aid of the Vellore college and hospital in South India is to be given in the Albert Hall at 7 30 P M, on Monday, April, 16, by the London Philharmonic Orchestra, conducted by Sir Adrian Boult, with Miss Eileen Joyce as the pianist Tickets can be obtained from the "Friends of Vellore," Annandale, North End Road, London, N W 11

Calling the Doctor

London local medical committee has expressed its concern at the increasing number of requests for visits received needlessly late in the day, thus preventing doctors from arranging their work to the best advantage Reporting to London Executive Council on March 22, the medical benefit committee observed that a patient who wishes his doctor to visit him is expected, if at all possible, to notify the practitioner before 10 A M The committee suggests that this requirement, which is already stated on all medical cards, should be widely publicised

Western Union Public-health Committee

At a meeting in Marseilles on March 20–22 the Brussels Treaty Public health Committee continued its study of the protection of the civil population's health in time of war and drew up a programme of work for the coming months The committee reviewed the programme of exchanges of medical and paramedical personnel of the five countries, which in 1950 enabled some forty doctors to travel in Western Union countries in order to study the general administrative structure of public health services Other subjects discussed included the standardisation of methods of control of food stuffs and proprietary medicines Finally, the committee took note of the entry into operation within the five Western Union countries of a uniform system of health control for sea traffic These measures complete the committee's work in this sphere since a similar organisation for the control of air traffic has already been established (see *Lancet*, 1950, i, 131)

Diets for Invalids

A new edition has been published of the Ministry of Food's memorandum for doctors setting out the arrangements for granting special rations and priority allowances of food The revised memorandum, which is known as Med 2 (1950), replaces Med 2 (Revised 1948) Doctors can obtain copies from their local food offices Newly qualified doctors will be sent copies as their names are added to the Medical Register

The Minister of Food announces that, on the recommendation of the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council, patients suffering from nephritis with gross œdema and albuminuria or from hypoproteinæmia are to be allowed six extra meat rations a week instead of four Patients under 5 years will now be allowed the same amount of meat as adult patients No increases have been recommended in the extra allowances of meat granted to patients suffering from diabetes mellitus hepatitis (acute infective or chronic), or steatorrhœa Patients with hypertension who are being treated with the Kempner rice diet may now be allowed three extra rations of sugar a week on cancellation of their bacon, cheese, and fat rations

National Marriage Guidance Council

The council have chosen Education for Marriage and Family Life as the theme of their fifth annual conference, which is to be held at Harrogate Hydro from May 17 to 21 Further particulars may be had from the secretary of the council, 78, Duke Street, London, W 1

Wessex Rahere Club

The spring dinner of this club will be held at the Royal Clarence Hotel, Exeter, at 7 30 P M, on Saturday, April 21 Prof L P Garrod will be guest of honour Membership of the club is open to old Barts men resident in the west country The secretary is Mr A Daunt Bateman, 3, The Circus, Bath

Manx Hospital Extensions

The foundation stone of a new nurses' home at Noble's Hospital, Douglas, Isle of Man, was laid by Air Vice Marshal Sir Geoffrey Bromet, the lieutenant-governor of the island, on March 15 The home is to cost £157,000, and will have accommodation for 138 sisters and nurses

Plans were also on view at the hospital of a new children's wing, which will take 50 children in small wards of not more than four beds each The Cubbon wing, provided by members of the Cubbon family at a cost of £41,000, is expected to be ready in July or August It will provide 30 beds for convalescents The hospital has a waiting list of 300, of which 50 are children

---

Prof John McMichael and Prof C Lovatt Evans, F R S, are visiting Madrid and Barcelona, under the auspices of the British Council, to advise on medical education in Spain

FADS AND FANCIES
THIRTY YEARS OF TUBERCULOSIS*

CHARLES CAMERON
M.A , M.D Glasg , F.R C.P.E , F R.F.P S , D.P H
PROFESSOR OF TUBERCULOSIS IN THE UNIVERSITY OF EDINBURGH

IT is salutary to look back in Medicine Its path is strewn with discarded theories and treatments which held the field for short and credulous periods , and when some are thrown up again by the whirligig of time, a knowledge of the part which they have played in the evolution of our ideas is always helpful It is often chastening When orthodox medicine fails, unorthodox methods appear , and that is easy enough to understand. What we often do not recognise is the frequency with which ill founded theories become accepted by the orthodox, and how ideas of slender foundation may dominate for a time a whole branch of medicine The fact that ideas or treatments have been discarded does not mean that they were ill founded or completely without results. They may have been followed by better ideas or treatments Sometimes they are unjustly displaced, and in the process much that was good becomes forgotten Today I wish to look back on thirty years of tuberculosis and on the changes which have taken place in that time

REST

In these remote days little of a specific nature could be done for the disease—I speak now of pulmonary tuberculosis—and indirect methods of treatment were exploited until they became a ritual. The days of unlimited exercise were passing The era of rest had dawned, and rest in these days meant what the word implied Today the jargon of "strict bed" has as much meaning as the slang of its expression Then absolute rest meant rest on the back without a pillow, and a vegetative existence which was prolonged until all clinical evidence pointed to a slowing down of the disease process, with healing and repair We know that this rest did not close huge cavities , but many a patient survived for years with cavities rendered quiescent, and many a very ill patient reached a stage of stabilisation of his disease There were theories at the time just as there are theories today, but the theories of today rest on better foundations and are worthy of careful thought by those who have not given any consideration to them The needle and the operation play a necesssary part in our work, but they would play a still better part if the lessons of the era of true rest were better known and better understood

The dynamics of the low-pressure pulmonary circulation demand true horizontal rest in the healing of pulmonary disease Such rest is difficult to secure in these days with their nursing difficulties, but patients should at least be told that the position to adopt in bed is the horizontal, not the vertical which is so commonly adopted and approved. Is it too much to ask that the bed rest should be used by prescription, and is it too much to suggest that the virtues of the tipped up beds, with patients all lying in one plane, are to be found in that very rest and modification of the pulmonary circulation which I have described ?

Is it too much to suggest that clinical methods still have a part to play in tuberculosis, that there are right and wrong ways of taking temperatures and that in consequence there are informative and uninformative temperature charts that the X ray film is extremely difficult to interpret, that much imaginative pathology often goes to its reading, and that it is merely an accessory, albeit important, method which Science has placed at our disposal ? Is it, in fact, too much to suggest that we should be first and foremost physicians, and not traders on the work of technicians ?

DIET

Thirty years ago the stuffing habit had passed A war had led to food shortages, and necessity had modified ideas previously current The knowledge of nutrition was growing, and elaborate dieting tended to take a secondary place in treatment Grumbling about food was perhaps even commoner in sanatoria than it is today Now we talk little of diet, and I wonder if we don't think even less about it The dietitian holds the field and saves us a lot of thinking on the foundations of life

We have been taught to be grateful for our mercies, and there is a tendency to forget the qualitative aspects of food We agreed long ago that excess of *fat* was difficult to digest and unnecessary for the consumptive After that we probably stopped thinking altogether, for it has recently been asked quite seriously if fat is necessary at all It is a fair assumption that, when Nature has made provision for dealing with fat, fat is necessary for maintenance of efficiency and health Apart from calorie and vitamin loss, lack of fat leads in fact to great loss of physical efficiency Twenty-four years ago, in the *Lancet* of Jan 8 1927, there appeared an article by W D Vaile, practitioner medical officer to the Church Army Sanatorium for Boys near Aldershot, which led to a great deal of subsequent controversy Under the heading of "Pulmonary Tuberculosis a Simple Preventive" Vaile propounded the view, founded on careful observation of families infected with tuberculosis, that those members who ate fat escaped overt disease while those who would not eat fat developed it The findings did not hold in every case—nothing ever does—but they did in the majority, and I wonder if we are not today missing something simple I am not thinking of the curative value, or otherwise, of excess of fat in sanatorium dietaries but of the preventive value of a proper supply of fat in the everyday diet Fat has not been abundant during the war and subsequent years, and more and more young people seem to be taught to reject the fats of meat as unfit for consumption

How many of you are familiar with the *Gerson diet* or its Sauerbruch-Herrmannsdorfer modification ? How many of us pause to reflect that the constitution of a diet may not only affect general nutrition and health but may have a profound effect on local tissue reactions ? We know the effects of certain diets on water retention, and we are familiar clinically with the fat flabby child fed on excess of carbohydrate, prone to eczema, rhinorrhœa, and hypertrophy of adenoid tissue Some of us know that certain of the allergic phenomena of tuberculous infection and disease—for example severe phlyctenular conjunctivitis—can be modified by eliminating, as far as possible, starch from the diet and replacing it by protein and fresh vegetables and fruit , and it was on a similar basis that Gerson introduced his diet He did so originally for the treatment of migraine and he found that it had a favourable effect on associated tuberculous conditions

Gerson was a country doctor As such his views were bound sooner or later to be suspect, and when he staked his claims over too wide a field the inevitable happened His first publication appeared in 1924, and his diet, which was salt-free, poor in carbohydrate and protein, and rich in fat, and contained a large allowance of raw vegetables and fruit, and was supplemented by cod liver oil, was claimed to have a curative value in a large number of diseases Sauerbruch and Herrmannsdorfer later modified the diet and Gerson was submerged by these two more scientific personalities They however made for the modified diet more rational and modest claims which were based on careful experimental work, principally on the healing of wounds and of tuberculous tissues. The application of the diet to tuberculosis showed it to have a profound effect on the healing of lupus and scrofuloderma, and a less defined effect on other forms of the disease; and there was little doubt that the course of some tuberculous lesions could be modified favourably by its use.

---

* An address delivered to the Tuberculosis Society of Scotland on Jan. 26

The fires of controversy over the Gerson diet have long been extinguished. More specific methods have come along; but with the death of the Gerson diet there died in tuberculosis an idea, to which I shall refer later, that in our attack on disease the basic structure and function of the cell must never be forgotten. We are the product of what we consume, and diet can alter tissue reactions to disease. The frontal is not the only method of approach or attack.

TUBERCULIN

There were two phases in the history of tuberculin. The first started in 1890 when Koch distributed his original tuberculin to a group of clinical workers of whom Robert Philip was one. It was employed by these men in the large doses which were believed at the time to be correct, and innumerable disasters led to its speedy abandonment. In the words of the report of the Tuberculin Treatment Subcommittee of the Brompton Hospital published in 1905, it was found to promote the formation of cavities, to lead to extension of the disease, to exhaust the patient, and to cause loss of strength and weight. In all too many it caused death. Some people at that time saw the potentialities of tuberculin if used in proper doses, but they were few in number and their advice fell on the deaf ears of a profession which was startled by a catastrophe.

In Germany a revival came in 1901 with the publication of clinical work based on a system of modified increasing dosage, and before 1910 the use of tuberculin in treatment was widespread. In England it was the researches of Almroth Wright into the mechanism of immunisation by bacteria and their products, and his specific recommendation in 1903 of tuberculin in the treatment of localised tuberculous lesions, which led to its reintroduction.

When I took up tuberculosis work some thirty two years ago, tuberculin was quite widely used; but the variety of forms employed and the varying beliefs in the virtues of the different types compelled one to view it critically. This aspect of the value of tuberculin is often enough portrayed. What is not portrayed is that it was the troublesome reactions which tuberculin caused which led to the constant search for more highly purified and supposedly safer products. None of these in time was shown to have any advantage over Koch's original Old Tuberculin, which ultimately became the standard form and was employed both in diagnosis and treatment.

There were theories about the use of tuberculin, and the workers of that period knew as much about it as we do today. The term "tuberculin sensitiveness" was used in a correct sense long before von Pirquet coined the word "allergy." It is often forgotten that Koch stated emphatically that tuberculin does not kill the bacilli present in the tissues, but that the tissue alone which encloses the bacilli is affected by the action of the remedy. In it, he said, there occurred well marked circulatory disturbances and great metabolic changes, resulting often in necrosis and the casting of a slough which in superficial lesions may as we know lead to cure. This is of course the well known focal allergic reaction, and its comparative safety in superficial glandular and skin lesions, and its danger in lung and ocular lesions, is readily appreciated. It was not a treatment which could be standardised and left to routine administration. Each patient presented his own problems with his own sensitivity, and it was the trouble to which tuberculin treatment gave rise and its potential dangers, not its lack of efficacy, which led to its ultimate abandonment.

Until quite recently tuberculin was practically discredited as a therapeutic agent, and those who condemned it were very often those who had never used it and had hardly read a line about it. Rich dismisses it as a desensitising agent which removes allergy from the path of immunity, and he dismisses the possibility of the focal reaction exercising a healing influence. One might have left the question of tuberculin treatment at that had the revolutions of time not brought it round again. Last August Honor Smith and R. L. Vollum from Sir Hugh Cairns' Oxford Surgical Unit published their work on the treatment of tuberculous meningitis with intrathecal injections of streptomycin and the purified protein derivative (P.P.D.) form of tuberculin. I do not propose to do any more than refer to this interesting work. The virtue of tuberculin causes no surprise to those who have employed it and have given critical thought to its use; but it disturbs me to learn that many are now using this combined form of treatment who know nothing of tuberculin itself. In their discussion of the action of intrathecally administered tuberculin Smith and Vollum give full consideration to Rich's desensitising theory but state that at the same time there is some indication that the acute inflammatory reaction provoked by the tuberculin is in itself beneficial—perhaps because it activates a fibrinolytic process and brings streptomycin or the natural humoral and chemical defence mechanisms into closer contact with the site of infection.

If we are on the threshold of another tuberculin era I hope fervently that none will enter who have not read Koch's work and the excellent works on tuberculin which appeared in the first decade of the century.

DIAPLYTE TUBERCULIN

There have been fancies in tuberculin, and one of the most recent—itself witness to the problems raised by its use—was the diaplyte tuberculin of Prof. Georges Dreyer of Oxford. In 1923 Dreyer published in the *British Medical Journal* under the heading "A Specific Treatment of Tuberculosis" an abstract of a report on new principles in bacterial immunity and their application in respiratory infections including tuberculosis. He pointed out that vaccines had succeeded chiefly in diseases caused by non acid fast and gram negative organisms. Postulating that the waxy and fatty substances present in such bacteria protected the specific bacterial proteins and prevented their liberation from the body of the bacterium, thus checking or stopping the production of an adequate stimulus for the immunity reaction of the infected host, Dreyer concluded that if these substances could be removed without damaging the proteins of the bacteria the latter might become suitable for immunising purposes. To this end he devised the following procedure: after preliminary treatment with formalin the organisms were extracted with acetone and the residuum was suspended in saline and used as a vaccine. In the case of the tubercle bacillus this was his diaplyte vaccine or tuberculin.

Dreyer's name carried great authority and the vaccine was tried in London hospitals by several competent physicians. It is interesting that it was introduced as a vaccine and recommended for treatment. After the publication of a series of cases treated by L. S. T. Burrell of the Brompton Hospital, the Medical Research Council carried out an investigation which had obviously not been planned by statisticians. Most of the publications on the use of the vaccine were uncritical, and the investigations of the Medical Research Council merely elicited a number of conflicting results.

Diaplyte tuberculin is probably the last chapter in the story of tuberculin as a therapeutic agent. It is a story with confused issues, and tuberculin finally became discredited partly because of careless work and partly by the prejudice which it aroused It was a substance which was not without danger and its potentialities for good were soon forgotten

TUBERCLE VACCINES

Almroth Wright's work ushered in the vaccine era, and the vaccine of those days was looked upon as something which might stimulate an immune response during the course of the disease It was inevitable that hopes of success in tuberculosis should arise, and when orthodox methods failed unorthodox methods entered the field The danger of the living virulent organism was always well known, but any attempts to affect the viability of the living organism by heat or chemical methods interfered with its antigenic properties There arose then the idea of using a type of bacillus from another species, and one of the best known vaccines of this type was the bovo vaccine of von Behring, which consisted of human tubercle bacilli and was used intravenously for the immunisation of cattle The reverse process—the use of living bovine organisms in humans—was naturally impossible, but the idea remained

Friedmann's turtle vaccine was a perfectly reputable preparation It was made from a tubercle bacillus isolated by Friedmann in 1903 from the lungs of a tuberculous sea turtle It was said to be antigenic for man and free from danger, and it was administered as a prophylactic much as B C G is used now It was used also as a therapeutic agent in early lung tuberculosis and tuberculosis of bones and joints One full session of the annual meeting of the Tuberculosis Association held in June, 1929, was devoted to a discussion of the vaccine, the principal speaker being Dr Franz Nagelschmidt, of Berlin, who put forward a strong case for its use but failed to convince his audience Calmette had already expressed doubts as to whether the organism was in fact a tubercle bacillus of reptilian origin, and (I speak from memory) I believe that the final verdict was that it was *not* a tubercle bacillus at all. B C G took the field and very little was heard of the turtle vaccine after this meeting, but in its lifetime it led to a great volume of experimental and investigational work

From 1925 to 1932 the long *Spahlinger* controversy raged, and during these years it was very difficult to disentangle facts from hypotheses and prejudice from belief

Henri Spahlinger was a Swiss who abandoned the study of Medicine, founded the Bacterio-Therapeutic Institute at Carouge, near Geneva, and devoted much time to the bacteriology of tuberculosis. He prepared an elaborate treatment of tuberculosis, the details of which varied from time to time—a fact which made it very difficult to follow such particulars as Spahlinger made public

The treatment was first used in this country by Dr Henry Latham on a number of his private patients during the winter of 1913–14, but little more was heard of it here until 1921 In 1922, as a result of press clamour, the British Red Cross, on M Spahlinger's statement that he had come to the end of his financial resources, voted £30,000 to be offered to him for the right to distribute his preparations in this country Spahlinger replied that he could not possibly produce the large number of doses required, and this was probably true After pressure in Parliament, the Ministry of Health offered to appoint an impartial committee of recognised medical authorities to observe the treatment in a series of cases of tuberculosis, leaving the selection of the cases to a physician to be nominated by Spahlinger himself This offer was declined In the same year (1922) in response to the persistent requests of the *Lancet*, Spahlinger published in that journal an account of his products and his methods of using them

This article is difficult to follow, but it seemed that he employed at least three so-called partial sera prepared from horses inoculated with different "toxins" of the tubercle bacillus which were produced in media "under varying types of physicochemical stimulation applied at definite intervals." Three partial sera were obtained in this way and were combined to form his antituberculosis serum A somewhat elaborate technique for the dosage and intervals of dosage was given In addition to this purely passive method, active immunisation was carried out in cases of chronic pulmonary tuberculosis and in non-pulmonary forms of the disease, and here he claimed to have isolated various antigenic fractions of the organism which he injected separately The whole process was suspiciously elaborate, and he stated further that the different bacterial fractions were injected separately so as to secure a series of immunities against all the deleterious products of bacterial disintegration This calls to mind Much's partial antigens which had no success and were soon abandoned

Spahlinger gained strong and influential adherents in this country In 1926 the science committee of the British Medical Association issued a statement and gave their blessing to an appeal which was being launched for funds to enable him to proceed with his work, but at the same time they pointed out the fallacies of many of his theories and expressed scepticism about his antisera In 1927 the central committee of the Fédération des Médecins Suisses sent a letter to the president of the British Medical Association stating that Spahlinger's methods had been tried by only a few individual Swiss doctors and that the contents and methods of preparation of his sera and vaccines were unknown to the Swiss profession The letter stated that the Geneva Medical Society had no more extensive or accurate information at its disposal This did not end the controversy which dragged on through certain immunising experiments in cattle until finally its impetus seemed to slacken and public interest disappeared

The impression left by this long-drawn-out affair was of a man trained in scientific methods but without any knowledge of medicine working on purely theoretical lines and creating furore and controversy in this country alone The rest of the world—with the exception of New South Wales, which sent a doctor to investigate the work—seemed to have little interest in the controversy and less in Spahlinger himself

It is very unlikely that we shall ever hear any more of diaplyte tuberculin, of turtle vaccines, or of Spahlinger's methods, but although all were fancies all were based on the idea, which dominated the vaccine era, of stimulating by specific methods the natural defence reactions of the body

TREATMENT BY LIGHT

I wonder how many of you were interested in the development of treatment by artificial light and I wonder how many of you have read Rollier's fascinating book on heliotherapy—this is its title—and know that it was the visit of Axel Reyn of the Finsen Institute to the annual meeting of the British Medical Association in 1923 which started a great wave of enthusiasm for the ultraviolet light treatment of tuberculous conditions In this country summers are short and sunshine is uncertain The easy applicability of the artificial product made an instant appeal, and the demand for lamps at first outstripped the supply Manufacturers, however, were not slow in their development of lamps to meet all purposes, and very soon few institutions were without their light rooms

The wave of enthusiasm has now, I think, largely spent itself. The administration of light treatment has passed to the physiotherapist and faith in its virtue seems to be half hearted. Yet those of us who worked in these days when we had to be physician, surgeon, and technician learned much of what this form of radiant energy could achieve and of its effects upon health and disease It was something which influenced the reactions of the body and its power of resistance, and its passing can only be regretted

This was no fad It was something of great value, and if it is disappearing from our armoury the fault lies with us and not with it

METHODS OF COLLAPSE AND OTHER SURGICAL MEASURES

Thirty years ago the average tuberculosis physician had barely heard of artificial pneumothorax, although principally on the healing of wounds and of tuberculous tissues The application of the diet to tuberculosis showed it to have a profound effect on the healing of lupus and scrofuloderma, and a less defined effect on other forms of the disease, and there was little doubt that the course of some tuberculous lesions could be modified favourably by its use

The fires of controversy over the Gerson diet have long been extinguished More specific methods have come along, but with the death of the Gerson diet there died in tuberculosis an idea, to which I shall refer later, that in our attack on disease the basic structure and function of the cell must never be forgotten We are the product of what we consume, and diet can alter tissue reactions to disease The frontal is not the only method of approach or attack

TUBERCULIN

There were two phases in the history of tuberculin The first started in 1890 when Koch distributed his original tuberculin to a group of clinical workers of whom Robert Philip was one It was employed by these men in the large doses which were believed at the time to be correct, and innumerable disasters led to its speedy abandonment In the words of the report of the Tuberculin Treatment Subcommittee of the Brompton Hospital published in 1905, it was found to promote the formation of cavities, to lead to extension of the disease, to exhaust the patient, and to cause loss of strength and weight In all too many it caused death Some people at that time saw the potentialities of tuberculin if used in proper doses, but they were few in number and their advice fell on the deaf ears of a profession which was startled by a catastrophe

In Germany a revival came in 1901 with the publication of clinical work based on a system of modified increasing dosage, and before 1910 the use of tuberculin in treatment was widespread In England it was the researches of Almroth Wright into the mechanism of immunisation by bacteria and their products, and his specific recommendation in 1903 of tuberculin in the treatment of localised tuberculous lesions, which led to its reintroduction

When I took up tuberculosis work some thirty two years ago, tuberculin was quite widely used, but the variety of forms employed and the varying beliefs in the virtues of the different types compelled one to view it critically This aspect of the value of tuberculin is often enough portrayed What is not portrayed is that it was the troublesome reactions which tuberculin caused which led to the constant search for more highly purified and supposedly safer products None of these in time was shown to have any advantage over Koch's original Old Tuberculin, which ultimately became the standard form and was employed both in diagnosis and treatment

There were theories about the use of tuberculin, and the workers of that period knew as much about it as we do today The term "tuberculin sensitiveness" was used in a correct sense long before von Pirquet coined the word "allergy" It is often forgotten that Koch stated emphatically that tuberculin does not kill the bacilli present in the tissues, but that the tissue alone which encloses the bacilli is affected by the action of the remedy In it, he said, there occurred well marked circulatory disturbances and great metabolic changes, resulting often in necrosis and the casting of a slough which in superficial lesions may as we know lead to cure This is of course the well known focal allergic reaction, and its comparative safety in superficial glandular and skin lesions, and its danger in lung and ocular lesions, is readily appreciated It was not a treatment which could be standardised and left to routine administration Each patient presented his own problems with his own sensitivity, and it was the trouble to which tuberculin treatment gave rise and its potential dangers, not its lack of efficacy, which led to its ultimate abandonment

Until quite recently tuberculin was practically discredited as a therapeutic agent, and those who condemned it were very often those who had never used it and had hardly read a line about it Rich dismisses it as a desensitising agent which removes allergy from the path of immunity, and he dismisses the possibility of the focal reaction exercising a healing influence One might have left the question of tuberculin treatment at that had the revolutions of time not brought it round again Last August Honor Smith and R L Vollum from Sir Hugh Cairns' Oxford Surgical Unit published their work on the treatment of tuberculous meningitis with intrathecal injections of streptomycin and the purified protein derivative (P P D) form of tuberculin I do not propose to do any more than refer to this interesting work The virtue of tuberculin causes no surprise to those who have employed it and have given critical thought to its use, but it disturbs me to learn that many are now using this combined form of treatment who know nothing of tuberculin itself In their discussion of the action of intrathecally administered tuberculin Smith and Vollum give full consideration to Rich's desensitising theory but state that at the same time there is some indication that the acute inflammatory reaction provoked by the tuberculin is in itself beneficial —perhaps because it activates a fibrinolytic process and brings streptomycin or the natural humoral and chemical defence mechanisms into closer contact with the site of infection

If we are on the threshold of another tuberculin era I hope fervently that none will enter who have not read Koch's work and the excellent works on tuberculin which appeared in the first decade of the century

DIAPLYTE TUBERCULIN

There have been fancies in tuberculin, and one of the most recent—itself witness to the problems raised by its use—was the diaplyte tuberculin of Prof. Georges Dreyer of Oxford In 1923 Dreyer published in the *British Medical Journal* under the heading "A Specific Treatment of Tuberculosis" an abstract of a report on new principles in bacterial immunity and their application in respiratory infections including tuberculosis He pointed out that vaccines had succeeded chiefly in diseases caused by non acid fast and gram negative organisms Postulating that the waxy and fatty substances present in such bacteria protected the specific bacterial proteins and prevented their liberation from the body of the bacterium, thus checking or stopping the production of an adequate stimulus for the immunity reaction of the infected host, Dreyer concluded that if these substances could be removed without damaging the proteins of the bacteria the latter might become suitable for immunising purposes To this end he devised the following procedure after preliminary treatment with formalin the organisms were extracted with acetone and the residuum was suspended in saline and used as a vaccine In the case of the tubercle bacillus this was his diaplyte vaccine or tuberculin

Dreyer's name carried great authority and the vaccine was tried in London hospitals by several competent physicians It is interesting that it was introduced as a vaccine and recommended for treatment After the publication of a series of cases treated by L S T Burrell of the Brompton Hospital, the Medical Research Council carried out an investigation which had obviously not been planned by statisticians Most of the publications on the use of the vaccine were uncritical, and the investigations of the Medical Research Council merely elicited a number of conflicting results

Diaplyte tuberculin is probably the last chapter in the story of tuberculin as a therapeutic agent It is a story with confused issues, and tuberculin finally became discredited partly because of careless work and partly by the prejudice which it aroused It was a substance which was not without danger and its potentialities for good were soon forgotten

TUBERCLE VACCINES

Almroth Wright's work ushered in the vaccine era, and the vaccine of those days was looked upon as something which might stimulate an immune response during the course of the disease It was inevitable that hopes of success in tuberculosis should arise, and when orthodox methods failed unorthodox methods entered the field The danger of the living virulent organism was always well known, but any attempts to affect the viability of the living organism by heat or chemical methods interfered with its antigenic properties There arose then the idea of using a type of bacillus from another species, and one of the best known vaccines of this type was the bovo-vaccine of von Behring, which consisted of human tubercle bacilli and was used intravenously for the immunisation of cattle The reverse process—the use of living bovine organisms in humans—was naturally impossible, but the idea remained

Friedmann's turtle vaccine was a perfectly reputable preparation It was made from a tubercle bacillus isolated by Friedmann in 1903 from the lungs of a tuberculous sea turtle It was said to be antigenic for man and free from danger, and it was administered as a prophylactic much as B C G is used now It was used also as a therapeutic agent in early lung tuberculosis and tuberculosis of bones and joints One full session of the annual meeting of the Tuberculosis Association held in June, 1929, was devoted to a discussion of the vaccine, the principal speaker being Dr Franz Nagelschmidt, of Berlin, who put forward a strong case for its use but failed to convince his audience Calmette had already expressed doubts as to whether the organism was in fact a tubercle bacillus of reptilian origin, and (I speak from memory) I believe that the final verdict was that it was not a tubercle bacillus at all. B C G took the field and very little was heard of the turtle vaccine after this meeting, but in its lifetime it led to a great volume of experimental and investigational work

From 1925 to 1932 the long *Spahlinger* controversy raged, and during these years it was very difficult to disentangle facts from hypotheses and prejudice from belief

Henri Spahlinger was a Swiss who abandoned the study of Medicine, founded the Bacterio-Therapeutic Institute at Carouge, near Geneva, and devoted much time to the bacteriology of tuberculosis He prepared an elaborate treatment of tuberculosis, the details of which varied from time to time—a fact which made it very difficult to follow such particulars as Spahlinger made public

The treatment was first used in this country by Dr Henry Latham on a number of his private patients during the winter of 1913–14, but little more was heard of it here until 1921 In 1922, as a result of press clamour, the British Red Cross, on M Spahlinger's statement that he had come to the end of his financial resources, voted £30,000 to be offered to him for the right to distribute his preparations in this country Spahlinger replied that he could not possibly produce the large number of doses required, and this was probably true After pressure in Parliament, the Ministry of Health offered to appoint an impartial committee of recognised medical authorities to observe the treatment in a series of cases of tuberculosis, leaving the selection of the cases to a physician to be nominated by Spahlinger himself This offer was declined In the same year (1922) in response to the persistent requests of the *Lancet*, Spahlinger published in that journal an account of his products and his methods of using them

This article is difficult to follow, but it seemed that he employed at least three so called partial sera prepared from horses inoculated with different "toxins" of the tubercle bacillus which were produced in media "under varying types of physicochemical stimulation applied at definite intervals." Three partial sera were obtained in this way and were combined to form his antituberculosis serum A somewhat elaborate technique for the dosage and intervals of dosage was given In addition to this purely passive method active immunisation was carried out in cases of chronic pulmonary tuberculosis and in non-pulmonary forms of the disease, and here he claimed to have isolated various antigenic fractions of the organism which he injected separately The whole process was suspiciously elaborate, and he stated further that the different bacterial fractions were injected separately so as to secure a series of immunities against all the deleterious products of bacterial disintegration This calls to mind Much's partial antigens which had no success and were soon abandoned

Until quite recently tuberculin was practically discredited as a therapeutic agent, and those who condemned it were very often those who had never used it and had hardly read a line about it Rich dismisses it as a desensitising agent which removes allergy from the path of immunity, and he dismisses the possibility of the focal reaction exercising a healing influence One might have left the question of tuberculin treatment at that had the revolutions of time not brought it round again Last August Honor Smith and R L Vollum from Sir Hugh Cairns' Oxford Surgical Unit published their work on the treatment of tuberculous meningitis with intrathecal injections of streptomycin and the purified protein derivative (P P D) form of tuberculin I do not propose to do any more than refer to this interesting work The virtue of tuberculin causes no surprise to those who have employed it and have given critical thought to its use, but it disturbs me to learn that many are now using this combined form of treatment who know nothing of tuberculin itself In their discussion of the action of intrathecally administered tuberculin Smith and Vollum give full consideration to Rich's desensitising theory but state that at the same time there is some indication that the acute inflammatory reaction provoked by the tuberculin is in itself beneficial —perhaps because it activates a fibrinolytic process and brings streptomycin or the natural humoral and chemical defence mechanisms into closer contact with the site of infection

If we are on the threshold of another tuberculin era I hope fervently that none will enter who have not read Koch's work and the excellent works on tuberculin which appeared in the first decade of the century

DIAPLYTE TUBERCULIN

There have been fancies in tuberculin, and one of the most recent—itself witness to the problems raised by its use—was the diaplyte tuberculin of Prof Georges Dreyer of Oxford In 1923 Dreyer published in the *British Medical Journal* under the heading " A Specific Treatment of Tuberculosis " an abstract of a report on new principles in bacterial immunity and their application in respiratory infections including tuberculosis He pointed out that vaccines had succeeded chiefly in diseases caused by non acid fast and gram negative organisms Postulating that the waxy and fatty substances present in such bacteria protected the specific bacterial proteins and prevented their liberation from the body of the bacterium, thus checking or stopping the production of an adequate stimulus for the immunity reaction of the infected host, Dreyer concluded that if these substances could be removed without damaging the proteins of the bacteria the latter might become suitable for immunising purposes To this end he devised the following procedure after preliminary treatment with formalin the organisms were extracted with acetone and the residuum was suspended in saline and used as a vaccine In the case of the tubercle bacillus this was his diaplyte vaccine or tuberculin

Dreyer's name carried great authority and the vaccine was tried in London hospitals by several competent physicians It is interesting that it was introduced as a vaccine and recommended for treatment After the publication of a series of cases treated by L S T Burrell of the Brompton Hospital, the Medical Research Council carried out an investigation which had obviously not been planned by statisticians Most of the publications on the use of the vaccine were uncritical, and the investigations of the Medical Research Council merely elicited a number of conflicting results

Diaplyte tuberculin is probably the last chapter in the story of tuberculin as a therapeutic agent It is a story with confused issues, and tuberculin finally became discredited partly because of careless work and partly the nature of suspicious lesions noted at necropsy, the rest were submitted simply because the occupational history or the clinical and radiological signs during life had raised the question of exposure to dust In the London area I often made the post mortem examination myself, but specimens were received from all parts of the country, generally accompanied by a summary of the necropsy findings

Most of the deceased persons had been in the same occupations for the greater part of their lives Skilled workers predominated, the majority being men Women were only met with to any great extent in the pottery and asbestos industries The dusts responsible were free silica, various silicates, clays, emery, iron, and various kinds of carbon (coal, graphite, soot, lamp black, and carbon black) Most of the workers were exposed to risks arising from mixed dust All the workers in the asbestos group had worked in the industry before the special regulations for the control of this dust came into force in 1932

METHOD

In the selection of tissue for section, portions from apparently healthy looking areas of lung were included whenever possible These often displayed the best early uncomplicated pneumoconiotic lesions, and were of particular value where malignant disease or tuberculosis complicated the picture The examination of hilum glands was also found to be important The standard paraffin embedding and staining techniques were employed as a routine, supplemented where necessary by frozen sections

TABLE I—PNEUMOCONIOSIS (ALL FORMS)

Group	Occupation	Silicosis	Other forms of pneumoconiosis	No pneumoconiosis	Total
1	Pottery workers	327	13	54	394
2	Coalminers	213	80	9	302
3	Asbestos workers	—	121	11	132
4	Stonemasons and quarriers	88	2	13	103
5	Iron and steel foundry workers metal grinders, and sandblasters of metal castings	75	3	24	102
6	Miscellaneous occupations and occupations not stated	93	21	58	172
	Total	796	240	169	1205

In statistical analysis of the cases the ages at death have been classified in three groups 15–44, 45–64, and 65 or more. Information as to the duration of exposure to dust was often incomplete Moreover, so many factors had to be taken into account in each case history—e g, illness and periods of unemployment and military service—that a comprehensive statistical investigation on this point seemed to be impracticable. Furthermore, the record of the population at risk was not available for such a varied group of workers over a period of twenty years, hence it was impossible to calculate the death rates Again, the occupational records of industrial pulmonary disease have increased greatly in complexity during this period, as more and more cases have come under review. The first detailed classification of occupations was made by Middleton (1936) The latest figures are given by the Chief Inspector of Factories (1949), who assigns the deaths from silicosis alone to no fewer than twenty four occupations It therefore seemed best in the present investigation to limit the classification to five large groups—(1) pottery workers, (2) coalminers (underground workers only), (3) asbestos workers, (4) stonemasons and quarriers, and (5) iron and steel foundrymen, metal grinders, and sandblasters of iron castings—and to assemble the remainder in a 6th group, miscellaneous occupations and occupations not stated

TABLE II—MEAN AGES AT DEATH

Occupation	Silicosis		Other forms of pneumoconiosis	
	No of patients whose ages were stated	Mean age (yr)	No of patients whose ages were stated	Mean age (yr)
Pottery workers	304*	53 2	12†	43 9
Coalminers	186	56 2	67	52 8
Asbestos workers Males	—	—	41	38 5
Females	—	—	61	33 5
Total	—	—	102	35 5
Stonemasons and quarriers	78	54 9	2	60 5
Iron and steel workers metal grinders and sandblasters	61	51·4	3	62 7
Miscellaneous occupations and occupations not stated	49	54 3	15	61·4
Total	678	54 3	201	43 1

* *Including 24 females* † *Including 1 female.*

ANALYSIS OF CASES

Of 1247 cases examined, 42 were deleted by reason of inadequate data, leaving 1205 for analysis Of these, 169 were negative for pneumoconiosis and 1036 positive. In the negative group, 111 persons had been engaged in industries with a recognised pneumoconiosis risk, whilst the remaining 58 had been exposed to various kinds of dust not known to carry this risk. The positives have been subdivided into examples of (1) silicosis with or without other forms of pneumoconiosis, and (2) other forms of pneumoconiosis The details of this classification are given in table I

Causes of Death

In the negative group the causes of death were chronic pulmonary tuberculosis 93 (55%), bronchiectasis 18 (10 7%), non industrial pulmonary fibrosis 15 (8 9%), primary malignant disease of the lung 14 (8 3%), pneumonia 5 (3%), miscellaneous respiratory diseases 6 (3 6%), and non respiratory diseases 18 (10 7%)

In the positive group 796 had silicosis and 240 other forms of pneumoconiosis Of the latter, 50 4% had asbestosis and 40 8% the dust reticulation type of lesion (of which 81 6% were coalminers) In the silicosis subgroup 21% had minimal lesions which had not been detected by naked eye

Ages at Death

The mean ages at death are given in table II.

Sex

The only pneumoconiosis group in which the number of females was sufficiently large for statistical analysis was that of asbestosis Here there were 52 males and 69 females The mean age at death for the males was 38 5 and for the females 33 5 In the males the highest percentage of deaths occurred in the 45–64 age group, as in other occupations, but in the females it was in the 15–44 group

Pneumoconiosis Accompanied by Tuberculosis

Table III shows that 43% of the 1036 cases of pneumoconiosis had active tuberculosis of the lungs also (58 6% of the cases of silicosis and 32% of the other forms of pneumoconiosis)

The highest incidence (64 1%) occurred in group 5 (iron and steel foundry workers, metal grinders, and sandblasters) and was due to the inclusion of 46 sandblasters with an incidence of 69 6% In spite of the fact that group 3 (asbestos workers) included a considerable number of young females (68 1% of the deaths in females occurred

Forlanini had published his first case in 1894 and in 1906 had reported the results of fourteen years' use My first pneumothorax was induced in 1924, and even then I had not even seen anyone else give a refill That was probably not long after the beginning of the era of surgical treatment in this country, and phrenic evulsion, adhesion cutting, and thoracoplasty had followed pneumothorax Indications for their use were often vague, and the thoracoplasty of the day was a serious operation We practised some of these treatments on indications which would not be accepted today, and the temporary popularity which phrenic evulsion enjoyed was a true surgical fancy Though the surgery of the lung and chest has evolved, and our indications are now more defined and precise, I often think that fads have not altogether passed

Pneumothorax fell under a cloud because of its mis application by uncritical, and even unskilled, people, and a few years ago it became fashionable to condemn it Pneumoperitoneum began to take its place because it seemed to lead to fewer complications, and much of the application of this undoubtedly valuable method of treatment was, and perhaps still is, of the nature of a fad We are now, I think, viewing things again in a truer perspective, but the enthusiasm for the tension theory of cavities and for ablation of lung tissue has its dangers, and fads still lie before us We must be progressive, but we must hold fast to our judgment

DRUGS

During these thirty years many drugs have flitted across the scene I remember well—it was the era of antiseptics and I acted under orders—when I used to inject iodoform and chinosol daily into the veins of consumptives, when I gave intramuscular injections of saccharose for reasons which I never quite understood, when 20 grains of potassium iodide was given in half a pint of water after breakfast followed four hours later by an ounce of aqua chlori in half a pint of fresh lemonade, repeated twice at two hourly intervals The chlorine was said to liberate iodine in the blood and the nascent iodine acted on the tuberculous foci It was a nice equation and it appeared in books There were others

What rubbish it must seem to those born into the era of sulphonamides and antibiotics, and how credulous must that generation seem to you! Yet are *you* bringing judgment to bear on the drugs which you use? Has it ever seemed to you that you are using the patient as a species of Aunt Sally at which you shy your streptomycin and P A S? Have the patients' tissues not a part to play? Are you not so obsessed with methods of frontal attack that you are forgetting the potentialities of the resistance movement? Is there, in fact, not also the important factor of host resistance, and, if there is, how much of what has been jettisoned in the past might profitably be reclaimed?

The past has lessons which we might well recall I am not pleading for the wholesale return of tuberculin or vaccines or of obsolete methods of treatment, but I do plead for a reconsideration of certain principles which we are tending to forget The old physicians who elaborated the true sanatorium régime were not fools, and methods which cured without treatment by collapse—which was in its infancy thirty years ago—and without modern drugs will reinforce powerfully our methods of today Why does calciferol cure lupus? It is probable that calcium plays only an intermediate part and that the vitamin per se has no direct action on the lesion It is more likely that the drug exercises an effect on cell metabolism and vascular endothelial permeability similar to what a discredited diet produced We do not know why some develop tuberculosis and others do not, and we hardly know on what immunity in tuberculosis is based, but the reversal of the body changes which go with a breakdown of immunity demands more than mechanical methods of treatment, and a reorientation of our views is overdue

THE DEATH RATE

These years have undoubtedly brought advances and we are wont to point with pride to a falling tuberculosis death rate as a product of our efforts I am the last to cast doubt on the efficacy of what we do, but it is difficult to correlate our efforts with the statistics of the past 80 years Tuberculosis in Scotland has been decreasing steadily since 1870, and apart from wars and pestilences nothing seems to have disturbed its course, although the rate of fall has been more uniform since 1918 when the tuberculosis provisions of the National Health Insurance Act became operative Now—when the number of deaths had risen and when by all utterances, semi official, municipal, and otherwise, things, under the schism of the National Health Service Act, were going from bad to worse, when everything, including beds, was failing us—the mortality has started suddenly to drop What has caused this sudden reversal? Tuberculosis is both an endemic and an epidemic, and if a secondary wave of the epidemic is now subsiding by natural causes let us accept the fact and be grateful for it Surely it were fancy to say that we have brought about this fall, but it is no fancy to say that we can help, for the tuberculosis epidemic has, like all epidemics, an infective side, and it is extremely susceptible to factors of national and local well being which we can perhaps in some way hope to influence Who can wield the greater influence here, the chest physician, or the sanitarian? Perhaps we are at this moment witnessing the establishment of the greatest fancy of all

There is much in the epidemiology of tuberculosis which we do not understand, and the disease has clinical aspects which we cannot explain Its treatment is no more static now than it was thirty years ago, and it is just as true today as it was then that everything that is new is not necessarily true or good There is still room for clinical observation and pathological study, and the better the judgment we bring to bear on these the more likely we shall be to advance our understanding of the many obscure problems which tuberculosis still presents.

PNEUMOCONIOSIS

A HISTOLOGICAL SURVEY OF NECROPSY MATERIAL IN 1205 CASES

S Roodhouse Gloyne *
M D Leeds, D P H
CONSULTING PATHOLOGIST, LONDON CHEST HOSPITAL AND KING EDWARD VII SANATORIUM, MIDHURST
From the Institute of Social Medicine, Oxford

THE meaning of the term pneumoconiosis is being enlarged year by year, and at the present time it is used to include pulmonary disease, both acute and chronic, attributable to many different kinds of dust In Statutory Instrument (1948) no 1371 the word is defined as " fibrosis of the lungs due to silica dust, asbestos dust or other dust, and includes the condition of the lungs known as dust reticulation but does not include byssinosis " In this paper the term is confined to this use

MATERIAL

The material reviewed here comprises a consecutive series of 1247 lungs, or portions thereof, received during the years 1920–49 for microscopical examination for the presence of pulmonary disease attributable to the inhalation of dust Most of the specimens were sent either to confirm the naked eye diagnosis or to determine the nature of suspicious lesions noted at necropsy, the rest were submitted simply because the occupational history or the clinical and radiological signs during life had raised the question of exposure to dust. In the London area I often made the post mortem examination myself, but specimens were received from all parts of the country, generally accompanied by a summary of the necropsy findings.

---

* Dr Gloyne was working with a grant from the Medical Research Council He died on Sept 25 1950

Most of the deceased persons had been in the same occupations for the greater part of their lives. Skilled workers predominated, the majority being men. Women were only met with to any great extent in the pottery and asbestos industries. The dusts responsible were free silica, various silicates, clays, emery, iron, and various kinds of carbon (coal, graphite, soot, lamp black, and carbon black). Most of the workers were exposed to risks arising from mixed dust. All the workers in the asbestos group had worked in the industry before the special regulations for the control of this dust came into force in 1932.

METHOD

In the selection of tissue for section, portions from apparently healthy-looking areas of lung were included whenever possible. These often displayed the best early uncomplicated pneumoconiotic lesions, and were of particular value where malignant disease or tuberculosis complicated the picture. The examination of hilum glands was also found to be important. The standard paraffin embedding and staining techniques were employed as a routine, supplemented where necessary by frozen sections.

TABLE I—PNEUMOCONIOSIS (ALL FORMS)

Group	Occupation	Silicosis	Other forms of pneumoconiosis	No pneumoconiosis	Total
1	Pottery workers	327	13	54	394
2	Coalminers	213	80	9	302
3	Asbestos workers	—	121	11	132
4	Stonemasons and quarriers	88	2	13	103
5	Iron and steel foundry workers metal grinders and sandblasters of metal castings	75	3	24	102
6	Miscellaneous occupations, and occupations not stated	93	21	58	172
	Total	796	240	169	1205

In statistical analysis of the cases the ages at death have been classified in three groups: 15–44, 45–64, and 65 or more. Information as to the duration of exposure to dust was often incomplete. Moreover, so many factors had to be taken into account in each case-history—e.g., illness and periods of unemployment and military service—that a comprehensive statistical investigation on this point seemed to be impracticable. Furthermore, the record of the population at risk was not available for such a varied group of workers over a period of twenty years; hence it was impossible to calculate the death rates. Again, the occupational records of industrial pulmonary disease have increased greatly in complexity during this period, as more and more cases have come under review. The first detailed classification of occupations was made by Middleton (1936). The latest figures are given by the Chief Inspector of Factories (1949), who assigns the deaths from silicosis alone to no fewer than twenty-four occupations. It therefore seemed best in the present investigation to limit the classification to five large groups—(1) pottery workers, (2) coalminers (underground workers only), (3) asbestos workers, (4) stonemasons and quarriers, and (5) iron and steel foundrymen, metal grinders, and sandblasters of iron castings—and to assemble the remainder in a 6th group, miscellaneous occupations and occupations not stated.

TABLE II—MEAN AGES AT DEATH

Occupation	Silicosis		Other forms of pneumoconiosis	
	No of patients whose ages were stated	Mean age (yr.)	No of patients whose ages were stated	Mean age (yr.)
Pottery workers	304*	53·2	12†	43·9
Coalminers	186	56·2	67	52·8
Asbestos workers Males	—	—	41	38·5
Females	—	—	61	33·5
Total	—	—	102	35·5
Stonemasons and quarriers	78	54·9	2	60·5
Iron and steel workers metal grinders and sandblasters	61	51·4	3	62·7
Miscellaneous occupations and occupations not stated	49	54·3	15	61·4
Total	678	54·3	201	43·1

* Including 24 females. † Including 1 female.

ANALYSIS OF CASES

Of 1247 cases examined, 42 were deleted by reason of inadequate data, leaving 1205 for analysis. Of these, 169 were negative for pneumoconiosis and 1036 positive. In the negative group, 111 persons had been engaged in industries with a recognised pneumoconiosis risk, whilst the remaining 58 had been exposed to various kinds of dust not known to carry this risk. The positives have been subdivided into examples of (1) silicosis with or without other forms of pneumoconiosis, and (2) other forms of pneumoconiosis. The details of this classification are given in table I.

Causes of Death

In the negative group the causes of death were chronic pulmonary tuberculosis 93 (55%), bronchiectasis 18 (10·7%), non-industrial pulmonary fibrosis 15 (8·9%), primary malignant disease of the lung 14 (8·3%), pneumonia 5 (3%), miscellaneous respiratory diseases 6 (3·6%), and non-respiratory diseases 18 (10·7%).

In the positive group 796 had silicosis and 240 other forms of pneumoconiosis. Of the latter, 50·4% had asbestosis and 40·8% the dust reticulation type of lesion (of which 81·6% were coalminers). In the silicosis subgroup 21% had minimal lesions which had not been detected by naked eye.

Ages at Death

The mean ages at death are given in table II.

Sex

The only pneumoconiosis group in which the number of females was sufficiently large for statistical analysis was that of asbestosis. Here there were 52 males and 69 females. The mean age at death for the males was 38·5 and for the females 33·5. In the males the highest percentage of deaths occurred in the 45–64 age group, as in other occupations, but in the females it was in the 15–44 group.

Pneumoconiosis Accompanied by Tuberculosis

Table III shows that 43% of the 1036 cases of pneumoconiosis had active tuberculosis of the lungs also (58·6% of the cases of silicosis and 32% of the other forms of pneumoconiosis).

The highest incidence (64·1%) occurred in group 5 (iron and steel foundry workers, metal grinders, and sandblasters) and was due to the inclusion of 46 sandblasters with an incidence of 69·6%. In spite of the fact that group 3 (asbestos workers) included a considerable number of young females (68·1% of the deaths in females occurred

Forlanini had published his first case in 1894 and in 1906 had reported the results of fourteen years' use. My first pneumothorax was induced in 1924, and even then I had not even seen anyone else give a refill. That was probably not long after the beginning of the era of surgical treatment in this country, and phrenic evulsion, adhesion cutting, and thoracoplasty had followed pneumothorax. Indications for their use were often vague, and the thoracoplasty of the day was a serious operation. We practised some of these treatments on indications which would not be accepted today, and the temporary popularity which phrenic evulsion enjoyed was a true surgical fancy. Though the surgery of the lung and chest has evolved, and our indications are now more defined and precise, I often think that fads have not altogether passed.

Pneumothorax fell under a cloud because of its misapplication by uncritical, and even unskilled, people, and a few years ago it became fashionable to condemn it. Pneumoperitoneum began to take its place because it seemed to lead to fewer complications, and much of the application of this undoubtedly valuable method of treatment was, and perhaps still is, of the nature of a fad. We are now, I think, viewing things again in a truer perspective, but the enthusiasm for the tension theory of cavities and for ablation of lung tissue has its dangers, and fads still lie before us. We must be progressive, but we must hold fast to our judgment.

DRUGS

During these thirty years many drugs have flitted across the scene. I remember well—it was the era of antiseptics and I acted under orders—when I used to inject iodoform and chinosol daily into the veins of consumptives, when I gave intramuscular injections of saccharose for reasons which I never quite understood, when 20 grains of potassium iodide was given in half a pint of water after breakfast followed four hours later by an ounce of aqua chlori in half a pint of fresh lemonade, repeated twice at two hourly intervals. The chlorine was said to liberate iodine in the blood and the nascent iodine acted on the tuberculous foci. It was a nice equation and it appeared in books. There were others.

What rubbish it must seem to those born into the era of sulphonamides and antibiotics, and how credulous must that generation seem to you! Yet are *you* bringing judgment to bear on the drugs which you use? Has it ever seemed to you that you are using the patient as a species of Aunt Sally at which you shy your streptomycin and P.A.S.? Have the patients' tissues not a part to play? Are you not so obsessed with methods of frontal attack that you are forgetting the potentialities of the resistance movement? Is there, in fact, not also the important factor of host resistance, and, if there is, how much of what has been jettisoned in the past might profitably be reclaimed?

The past has lessons which we might well recall. I am not pleading for the wholesale return of tuberculin or vaccines or of obsolete methods of treatment, but I do plead for a reconsideration of certain principles which we are tending to forget. The old physicians who elaborated the true sanatorium régime were not fools, and methods which cured without treatment by collapse—which was in its infancy thirty years ago—and without modern drugs will reinforce powerfully our methods of today. Why does calciferol cure lupus? It is probable that calcium plays only an intermediate part and that the vitamin per se has no direct action on the lesion. It is more likely that the drug exercises an effect on cell metabolism and vascular endothelial permeability similar to what a discredited diet produced. We do not know why some develop tuberculosis and others do not, and we hardly know on what immunity in tuberculosis is based, but the reversal of the body changes which go with a breakdown of immunity demands more than mechanical methods of treatment, and a reorientation of our views is overdue.

THE DEATH RATE

These years have undoubtedly brought advances and we are wont to point with pride to a falling tuberculosis death rate as a product of our efforts. I am the last to cast doubt on the efficacy of what we do, but it is difficult to correlate our efforts with the statistics of the past 80 years. Tuberculosis in Scotland has been decreasing steadily since 1870, and apart from wars and pestilences nothing seems to have disturbed its course, although the rate of fall has been more uniform since 1918 when the tuberculosis provisions of the National Health Insurance Act became operative. Now—when the number of deaths had risen and when by all utterances, semi-official, municipal, and otherwise, things, under the schism of the National Health Service Act, were going from bad to worse, when everything, including beds, was failing us—the mortality has started suddenly to drop. What has caused this sudden reversal? Tuberculosis is both an endemic and an epidemic, and if a secondary wave of the epidemic is now subsiding by natural causes let us accept the fact and be grateful for it. Surely it were fancy to say that we have brought about this fall, but it is no fancy to say that we can help, for the tuberculosis epidemic has, like all epidemics, an infective side, and it is extremely susceptible to factors of national and local well-being which we can perhaps in some way hope to influence. Who can wield the greater influence here, the chest physician, or the sanitarian? Perhaps we are at this moment witnessing the establishment of the greatest fancy of all.

There is much in the epidemiology of tuberculosis which we do not understand, and the disease has clinical aspects which we cannot explain. Its treatment is no more static now than it was thirty years ago, and it is just as true today as it was then that everything that is new is not necessarily true or good. There is still room for clinical observation and pathological study, and the better the judgment we bring to bear on these the more likely we shall be to advance our understanding of the many obscure problems which tuberculosis still presents.

PNEUMOCONIOSIS

A HISTOLOGICAL SURVEY OF NECROPSY MATERIAL IN 1205 CASES

S. ROODHOUSE GLOYNE[*]
M.D. Leeds, D.P.H.
CONSULTING PATHOLOGIST, LONDON CHEST HOSPITAL AND
KING EDWARD VII SANATORIUM, MIDHURST
From the Institute of Social Medicine, Oxford

THE meaning of the term pneumoconiosis is being enlarged year by year, and at the present time it is used to include pulmonary disease, both acute and chronic, attributable to many different kinds of dust. In Statutory Instrument (1948) no. 1371 the word is defined as "fibrosis of the lungs due to silica dust, asbestos dust or other dust, and includes the condition of the lungs known as dust reticulation but does not include byssinosis." In this paper the term is confined to this use.

MATERIAL

The material reviewed here comprises a consecutive series of 1247 lungs, or portions thereof, received during the years 1929–49 for microscopical examination for the presence of pulmonary disease attributable to the inhalation of dust. Most of the specimens were sent either to confirm the naked-eye diagnosis or to determine the nature of suspicious lesions noted at necropsy, the rest were submitted simply because the occupational history or the clinical and radiological signs during life had raised the question of exposure to dust. In the London area I often made the post mortem examination myself, but specimens were received from all parts of the country, generally accompanied by a summary of the necropsy findings.

---

[*] Dr. Gloyne was working with a grant from the Medical Research Council. He died on Sept. 25, 1950.

Most of the deceased persons had been in the same occupations for the greater part of their lives. Skilled workers predominated, the majority being men. Women were only met with to any great extent in the pottery and asbestos industries. The dusts responsible were free silica, various silicates, clays, emery, iron, and various kinds of carbon (coal, graphite, soot, lamp black, and carbon black). Most of the workers were exposed to risks arising from mixed dust. All the workers in the asbestos group had worked in the industry before the special regulations for the control of this dust came into force in 1932.

METHOD

In the selection of tissue for section, portions from apparently healthy-looking areas of lung were included whenever possible. *These often displayed the best early* uncomplicated pneumoconiotic lesions, and were of particular value where malignant disease or tuberculosis complicated the picture. The examination of hilum glands was also found to be important. The standard paraffin embedding and staining techniques were employed as a routine, supplemented where necessary by frozen sections.

Total		678	54·3	201	43·1

* Including 24 females. † Including 1 female.

ANALYSIS OF CASES

Of 1247 cases examined, 42 were deleted by reason of inadequate data, leaving 1205 for analysis. Of these, 169 were negative for pneumoconiosis and 1036 positive. In the negative group, 111 persons had been engaged in industries with a recognised pneumoconiosis risk, whilst the remaining 58 had been exposed to various kinds of dust not known to carry this risk. The positives have been subdivided into examples of (1) silicosis with or without other forms of pneumoconiosis, and (2) other forms of pneumoconiosis. The details of this classification are given in table I.

Causes of Death

In the negative group the causes of death were chronic pulmonary tuberculosis 93 (55%), bronchiectasis 18 (10·7%), non-industrial pulmonary fibrosis 15 (8·9%), primary malignant disease of the lung 14 (8·3%), pneumonia 5 (3%), miscellaneous respiratory diseases 6 (3·6%), and non respiratory diseases 18 (10·7%).

In the positive group 796 had silicosis and 240 other forms of pneumoconiosis. Of the latter, 50·4% had asbestosis and 40·8% the dust reticulation type of lesion (of which 81·6% were coalminers). In the silicosis subgroup 21% had minimal lesions which had not been detected by naked eye.

Ages at Death

The mean ages at death are given in table II.

Sex

The only pneumoconiosis group in which the number of females was sufficiently large for statistical analysis was that of asbestosis. Here there were 52 males and 69 females. The mean age at death for the males was 38·5 and for the females 33·5. In the males the highest percentage of deaths occurred in the 45–64 age group, as in other occupations, but in the females it was in the 15–44 group.

Pneumoconiosis Accompanied by Tuberculosis

Table III shows that 43% of the 1036 cases of pneumoconiosis had active tuberculosis of the lungs also (58·6% of the cases of silicosis and 32% of the other forms of pneumoconiosis).

The highest incidence (64·1%) occurred in group 5 (iron and steel foundry workers, metal grinders, and sandblasters) and was due to the inclusion of 46 sandblasters with an incidence of 69·6%. In spite of the fact that group 3 (asbestos workers) included a considerable number of young females (68·1% of the deaths in females occurred

TABLE III—PNEUMOCONIOSIS (ALL FORMS) ASSOCIATED WITH TUBERCULOSIS

Group	Occupation	No of cases of pneumo coniosis	No of cases with tuberculosis
1	Pottery workers	340	146 (42 94%)
2	Coalminers	293	100 (34 13%)
3	Asbestos workers	121	43 (35 54%)
4	Stonemasons and quarriers	90	18 (53 33%)
5	Iron and steel workers metal grinders and sandblasters of metal castings	78	50 (64 10%)
6	Miscellaneous occupations and occupations not stated	114	58 (50 88%)
	Total	1036	445 (43 95%)

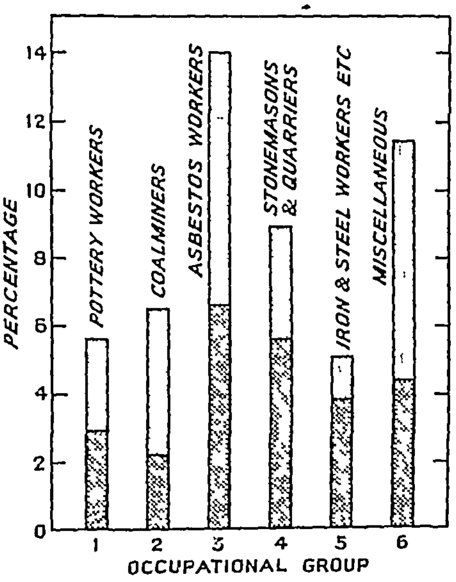
in the 15–44 age group), the incidence of tuberculosis for the whole of the asbestosis series was only 35 5% In 13 5% of the 445 cases of active pulmonary tuberculosis in all forms of pneumoconiosis, the tuberculous lesions were only detected on microscopy

Pneumoconiosis Accompanied by Malignant Disease

The incidence of malignant disease in the 1036 cases of pneumoconiosis is shown in the accompanying figure

Primary Neoplasm of the Lung —There were 80 cases of primary neoplasm of the lung distributed as follows 55 in the silicosis group (i e , 6 9%), 17 in the asbestosis group (i e , 14 1%), and 8 in the other forms of pneumoconiosis (i e , 6 7%) In the asbestosis group the rates for male and female workers were 19 6% and 9 7% respectively

The growths included 26 columnar cell, 52 squamous cell, and 2 oat cell In 6 cases (7 5%) the lesion was first discovered on microscopy



Malignant neoplasms associated with pneumoconiosis stippled columns, primary of lung cross-hatched columns other malignant growths at all sites other than lung

Neoplasm of other Sites —There were 37 cases with neoplasms at other sites, of which 30 were in the digestive tract and 7 elsewhere (14 were associated with secondary deposits in the lung) All were carcinomata except 1 hypernephroma and 1 tumour of the skull The asbestosis cases accounted for 8, of which 2 were in females

Pneumoconiosis Accompanied by Malignant Disease and Tuberculosis

Of the 80 cancers of the lung 15 (18 7%) had active pulmonary tuberculosis also, and of the 37 growths at other sites 8 (21 6%) had this combination of diseases

DISCUSSION

When the term pneumoconiosis is limited to fibrosis of the lung due to the inhalation of mineral dust, silicosis is the commonest form of the disease In the present series of necropsies it accounted for 796 cases (77%) Its characteristic whorled nodule of reticulin and collagenous fibres was best seen in the lungs of stonemasons and quarriers, where admixture of the silica with carbon dusts was less common than in other groups, but it was present in all cases in which silicosis was diagnosed. It was found in both discrete and conglomerate forms in the usual peribronchial, perivascular, subpleural, and interlobular sites, where the small lymphoid follicles, which are inconspicuous in the normal lung, arrest the silica particles, and it was the essential component of the massive fibrotic nodules which are so characteristic a feature of the radiograph With age, the fibres of this whorled nodule became more hyaline and less permeable to aniline dyes, but the nodule remains a diagnostic feature of the silicotic lung to the end

Many attempts have been made to grade cases of silicosis for compensation purposes on the basis of the size, number, and distribution of these nodules, but all these classifications are apt to be arbitrary and to break down in practice There is, however, good reason for reserving the term minimal silicosis for those lungs in which characteristic nodules are diagnosed only on histological examination Accompanying this nodule formation there was also an increase in the collagenous fibres which normally, as described by Snow Miller, surround the walls of the terminal portions of the bronchial airway and the accompanying branches of the pulmonary artery The geodetic arrangement of these fibres only becomes obvious in serial sections This type of irregular non nodular fibrosis lesion is most pronounced in mixed dust pneumoconiosis, and in the present state of our knowledge the part played in its formation by the different dusts is obscure

The term " infective silicosis " is also not infrequently used It is a vague phrase employed in different senses by different writers Some confine it to certain types of tuberculo silicosis , others enlarge it to include infections with other organisms which produce the intermittent pneumonias of silicosis The lesion has two main histological characteristics—namely, an excessive amount of non nodular fibrosis and a zone of cellular proliferation round the silicotic nodule The latter has been well depicted by Simson et al (1930) in the South African cases

Several writers have now described the histological lesion of asbestosis, with its characteristic asbestosis bodies and its reticular fibrosis of the primary lobule of the lung, where the long asbestosis fibre is held up athwart the terminal portion of the respiratory bronchiole, and the saccular dust Roughly whorled nodules may be encountered occasionally in cases of asbestosis where there has been no known exposure to silica—they were present in 7 cases in the present series—but asbestosis is usually a primary lobule rather than a peribronchial nodule fibrosis In long standing cases both the asbestos fibres and the asbestosis bodies were smaller and less often seen than in the lungs of workers more recently exposed to asbestos, suggesting that in course of time the asbestos fibres are slowly dissolved

Dust reticulation, the type of mixed dust pneumoconiosis described by Belt and Ferris (1942) in coal miners, has now been found also in the lungs of potters, foundrymen (McLaughlin et al 1950), and other workers In introducing this term as a more detailed and precise portraiture of the original word anthracosis, Belt and Ferris laid stress on the reticulin element in the fibrosis, its characteristic distribution, and its ultimate development into a " reticulin nodulation " It is a tissue response to a mixed dust of which silica and coal are the chief ingredients, and shows that the place of coal may be taken by other forms of carbon—e g , graphite (Gloyne et al. 1949) Heppleston (1947) has described the basic early lesion as seen in the coalminer

Some of the other forms of pneumoconiosis in the present series have already been described elsewhere One was a reticular fibrosis resembling that of asbestosis, in which the lesion was produced by montmorillonite in a fuller's earth worker (Campbell and Gloyne 1942) Graphite has already been referred to With the extremely varied nature of industry in this country these unusual forms of pneumoconiosis will presumably increase in number, but they are hardly likely to displace silicosis as the most serious risk among diseases due to mineral dust

One of the chief difficulties encountered in the histological examination of the pneumoconiotic lung is the prevalence of mixed dusts in our factories The production of fibrosis of the lung by the inhalation of a pure dust belongs to the domain of the experimental pathologist It is doubtful how far such a condition exists in industry King et al. (1950) have done much to separate the components of these mixed dusts

The picture of pneumoconiosis described here therefore is that of a chronic tissue reaction to a mixed dust, the particles of which vary in size, solubility, and toxicity In the lung the drift of the particles is towards the hilum by way of the superficial and deep lymphatic drainage trunks which are the channels of communication between the terminal portions of the airway and the root glands The passage of these particles from airway to hilum is marked by a complicated protective tissue response at strategic points en route, and the relative importance of these defence posts varies, to some extent at least, with the size and nature of the component dusts In the case of the long needle like asbestos fibre, for example, the terminal portion of the respiratory bronchiole is the crucial site, with the minute silica particle it is the peribronchial and perivascular lymph node

In several types of pneumoconiosis the dust particles become coated with the plasma protein of the capillary exudate to form elongated segmented bodies of a golden yellow colour with a central core of dust particle They do not stain with the ordinary aniline dyes, but the potassium ferrocyanide test for iron turns them blue They were first described by Cooke and Stuart McDonald in 1927 in the lungs of an asbestos worker under the non committal term "curious bodies" Since then they have been found in the lungs of coalminers, graphite workers, and talc workers They are probably of no particular diagnostic significance except in the case of asbestosis, where they are sufficiently characteristic to form an essential part of the histological picture It would seem that the ætiology of all these bodies is now sufficiently understood to merit the abandonment of the vague term "curious bodies" in favour of a generic phrase—"pneumoconiosis bodies"

Until recently it was believed that the protective tissue reaction of the whole respiratory tract was such that the lung itself was called on to deal with probably not more than 25% of the inhaled dust particles, the rest being excreted by the upper respiratory tract and the extra pulmonary bronchi. The particles which reached the lung tissue were considered to be generally of the size of bacteria—i e, less than 10 μ With the development of the new techniques of X ray diffraction analysis and the electron microscope, however, study of an ultramicroscopic particle in the pneumoconiotic lesion is opening up, and a "lower limit of detectability" (King et al 1950) is now recognised The use of prophylactic dusts, such as aluminium, will also affect the histological picture in the near future

In view of the interference with the pulmonary circulation, the hæmo respiratory exchange, and the lymphatic drainage system it is not surprising that there should be a group of diseases so commonly associated with pneumoconiosis as to be an essential part of its pathology—e g, chronic bronchitis and emphysema, various types of cardiac failure, and the terminal bronchopneumonias Pathologically these are, for the most part, naked eye diagnoses which do not come within the scope of this paper Two others, however, are based on histological investigation—namely, tuberculosis and malignant disease Tuberculosis has long been recognised as ætiologically important in pneumoconiosis, but it is only within recent years that a high incidence of primary pulmonary carcinoma has been suspected

For pneumoconiosis of all forms, the incidence of 42 95% of tuberculosis in the present series may be compared with the figures for silicosis found by other investigators Thus in a series of necropsies on sandstone workers, Meiklejohn (1949) found that 44 3% of those with silicosis had tuberculosis also whilst in pottery workers the percentage was 40 Merewether (1936) found that of 38 sandblasters who had died of silicosis 28 (73 7%) also had tuberculosis The figure for this occupation in the present series is 69 6% Sandblasting has now been abolished in this country in favour of the less harmful operation of shot blasting, for which mortality figures are not yet available

No satisfactory control group has been found with which to compare the incidence (7 7%) of primary lung cancer in the 1036 cases of pneumoconiosis In the 169 cases which proved not to be pneumoconiosis the incidence was 8 3% In both groups, selection may have been exercised in picking out cases in which the radiographs and clinical histories had been unusual for an uncomplicated pneumoconiosis Bradford Hill and Lewis Faning (1948), investigating the mortality in an arsenic factory, noted a proportional and significant excess of deaths attributed to cancer of all sites (and especially of the lung and skin) in the arsenic workers (29%), compared with the mortality of three other occupational groups living in the same area (13%)

The necropsy records for 1928–39 at the London Chest Hospital, where selection is obviously at work in picking out these cases for special observation and treatment, show the high incidence of 151 primary lung cancers (21 3%) in 706 necropsies, whereas at the other end of the scale the Registrar General (1950) reports for 1948 2 4% (3 9% of males and 0 9% of females) of the deaths from all causes in the general population over the age of 15 as being due to primary malignant disease of the lung (all forms) This last figure is an increase on those of previous years Although comparable sets of statistics appear to be lacking, the evidence on all sides seems to point to an increase of deaths from primary cancer of the lung in the general population It seems reasonable to suppose that workers with a dust hazard have their share in this increase Whether they have a risk over and above this as a result of their occupation cannot yet be clearly shown, but the mortality of the asbestos workers is disturbing In the present series 14% of the patients with asbestosis also had primary cancer of the lung This is all the more striking because so many of them (41 2%) were females This proportion of female deaths is greater than that in the general population, where the incidence of primary cancer of the lung is 4 4 males to 1 female

The association of active pulmonary tuberculosis with cancer of the lung has been noted by several observers, both in general and in chest hospitals Simpson (1929) found active tuberculosis in 4 2% of the necropsies on cases of primary pulmonary carcinoma at the London Hospital, Maxwell (1930) in 5 4% at the Royal Chest Hospital and St Bartholomew's, Davidson (1930) in

TABLE III—PNEUMOCONIOSIS (ALL FORMS) ASSOCIATED WITH TUBERCULOSIS

Group	Occupation	No of cases of pneumo coniosis	No of cases with tuberculosis
1	Pottery workers	340	146 (*42 94%*)
2	Coalminers	293	100 (*34 13%*)
3	Asbestos workers	121	43 (*35 54%*)
4	Stonemasons and quarriers	90	48 (*53 33%*)
5	Iron and steel workers metal grinders and sandblasters of metal castings	78	50 (*64 10%*)
6	Miscellaneous occupations and occupations not stated	114	58 (*50 88%*)
	Total	1036	445 (*42 95%*)

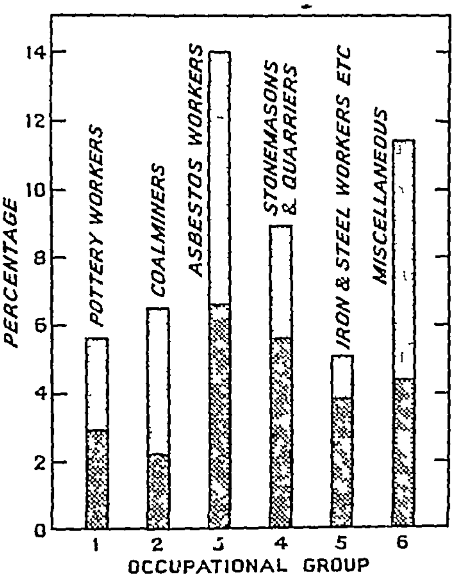
in the 15–44 age group), the incidence of tuberculosis for the whole of the asbestosis series was only 35 5% In 13 5% of the 445 cases of active pulmonary tuberculosis in all forms of pneumoconiosis, the tuberculous lesions were only detected on microscopy

Pneumoconiosis Accompanied by Malignant Disease

The incidence of malignant disease in the 1036 cases of pneumoconiosis is shown in the accompanying figure

Primary Neoplasm of the Lung—There were 80 cases of primary neoplasm of the lung distributed as follows 55 in the silicosis group (i e , 6 9%), 17 in the asbestosis group (i e , 14 1%), and 8 in the other forms of pneumoconiosis (i e , 6 7%) In the asbestosis group the rates for male and female workers were 19 6% and 9 7% respectively

The growths included 26 columnar cell, 52 squamous cell, and 2 oat cell In 6 cases (7 5%) the lesion was first discovered on microscopy



Malignant neoplasms associated with pneumoconiosis: stippled columns primary of lung cross-hatched columns other malignant growths at all sites other than lung

Neoplasm of other Sites—There were 37 cases with neoplasms at other sites, of which 30 were in the digestive tract and 7 elsewhere (14 were associated with secondary deposits in the lung) All were carcinomata except 1 hypernephroma and 1 tumour of the skull The asbestosis cases accounted for 8, of which 2 were in females

Pneumoconiosis Accompanied by Malignant Disease and Tuberculosis

Of the 80 cancers of the lung 15 (18 7%) had active pulmonary tuberculosis also, and of the 37 growths at other sites 8 (21 6%) had this combination of diseases

DISCUSSION

When the term pneumoconiosis is limited to fibrosis of the lung due to the inhalation of mineral dust, silicosis is the commonest form of the disease In the present series of necropsies it accounted for 796 cases (77%). Its characteristic whorled nodule of reticulin and collagenous fibres was best seen in the lungs of stonemasons and quarriers, where admixture of the silica with carbon dusts was less common than in other groups, but it was present in all cases in which silicosis was diagnosed. It was found in both discrete and conglomerate forms in the usual peribronchial, perivascular, subpleural, and interlobular sites, where the small lymphoid follicles, which are inconspicuous in the normal lung, arrest the silica particles, and it was the essential component of the massive fibrotic nodules which are so characteristic a feature of the radiograph With age, the fibres of this whorled nodule became more hyaline and less permeable to aniline dyes, but the nodule remains a diagnostic feature of the silicotic lung to the end

Many attempts have been made to grade cases of silicosis for compensation purposes on the basis of the size, number, and distribution of these nodules, but all these classifications are apt to be arbitrary and to break down in practice There is, however, good reason for reserving the term minimal silicosis for those lungs in which characteristic nodules are diagnosed only on histological examination Accompanying this nodule formation there was also an increase in the collagenous fibres which normally, as described by Snow Miller, surround the walls of the terminal portions of the bronchial airway and the accompanying branches of the pulmonary artery The geodetic arrangement of these fibres only becomes obvious in serial sections This type of irregular non nodular fibrosis lesion is most pronounced in mixed dust pneumoconiosis, and in the present state of our knowledge the part played in its formation by the different dusts is obscure

The term "infective silicosis" is also not infrequently used It is a vague phrase employed in different senses by different writers Some confine it to certain types of tuberculo silicosis, others enlarge it to include infections with other organisms which produce the intermittent pneumonias of silicosis The lesion has two main histological characteristics—namely, an excessive amount of non nodular fibrosis and a zone of cellular proliferation round the silicotic nodule The latter has been well depicted by Simson et al (1930) in the South African cases

Several writers have now described the histological lesion of asbestosis, with its characteristic asbestosis bodies and its reticular fibrosis of the primary lobule of the lung, where the long asbestosis fibre is held up athwart the terminal portion of the respiratory bronchiole, and the saccular dust Roughly whorled nodules may be encountered occasionally in cases of asbestosis where there has been no known exposure to silica—they were present in 7 cases in the present series—but asbestosis is usually a primary lobule rather than a peribronchial nodule fibrosis In long standing cases both the asbestos fibres and the asbestosis bodies were smaller and less often seen than in the lungs of workers more recently exposed to asbestos, suggesting that in course of time the asbestos fibres are slowly dissolved

Dust reticulation, the type of mixed dust pneumoconiosis described by Belt and Ferris (1942) in coal miners, has now been found also in the lungs of potters, foundrymen (McLaughlin et al 1950), and other workers In introducing this term as a more detailed and precise portraiture of the original word anthracosis, Belt and Ferris laid stress on the reticulin element in the fibrosis, its characteristic distribution, and its ultimate development into a "reticulin nodulation" It is a tissue response to a mixed dust of which silica and coal are the chief ingredients, and shows that the place of coal may be taken by other forms of carbon—e g , graphite (Gloyne et al. 1949). Heppleston (1947) has described the basic early lesion as seen in the coalminer.

Some of the other forms of pneumoconiosis in the present series have already been described elsewhere. One was a reticular fibrosis resembling that of asbestosis, in which the lesion was produced by montmorillonite in a fuller's earth worker (Campbell and Gloyne 1942). Graphite has already been referred to. With the extremely varied nature of industry in this country these unusual forms of pneumoconiosis will presumably increase in number, but they are hardly likely to displace silicosis as the most serious risk among diseases due to mineral dust.

One of the chief difficulties encountered in the histological examination of the pneumoconiotic lung is the prevalence of mixed dusts in our factories. The production of fibrosis of the lung by the inhalation of a pure dust belongs to the domain of the experimental pathologist. It is doubtful how far such a condition exists in industry. King et al. (1950) have done much to separate the components of these mixed dusts.

The picture of pneumoconiosis described here therefore is that of a chronic tissue reaction to a mixed dust, the particles of which vary in size, solubility, and toxicity. In the lung the drift of the particles is towards the hilum by way of the superficial and deep lymphatic drainage trunks which are the channels of communication between the terminal portions of the airway and the root glands. The passage of these particles from airway to hilum is marked by a complicated protective tissue response at strategic points en route, and the relative importance of these defence posts varies, to some extent at least, with the size and nature of the component dusts. In the case of the long needle-like asbestos fibre, for example, the terminal portion of the respiratory bronchiole is the crucial site; with the minute silica particle it is the peribronchial and perivascular lymph node.

In several types of pneumoconiosis the dust particles become coated with the plasma-protein of the capillary exudate to form elongated segmented bodies of a golden yellow colour with a central core of dust particle. They do not stain with the ordinary aniline dyes, but the potassium ferrocyanide test for iron turns them blue. They were first described by Cooke and Stuart McDonald in 1927 in the lungs of an asbestos worker under the non-committal term "curious bodies." Since then they have been found in the lungs of coalminers, graphite workers, and talc workers. They are probably of no particular diagnostic significance except in the case of asbestosis, where they are sufficiently characteristic to form an essential part of the histological picture. It would seem that the ætiology of all these bodies is now sufficiently understood to merit the abandonment of the vague term "curious bodies" in favour of a generic phrase—"pneumoconiosis bodies."

Until recently it was believed that the protective tissue reaction of the whole respiratory tract was such that the lung itself was called on to deal with probably not more than 25% of the inhaled dust particles, the rest being excreted by the upper respiratory tract and the extrapulmonary bronchi. The particles which reached the lung tissue were considered to be generally of the size of bacteria—i.e., less than 10 µ. With the development of the new techniques of X-ray diffraction analysis and the electron microscope, however, study of an ultramicroscopic particle in the pneumoconiotic lesion is opening up, and a "lower limit of detectability" (King et al. 1950) is now recognised. The use of prophylactic dusts, such as aluminium, will also affect the histological picture in the near future.

In view of the interference with the pulmonary circulation, the hæmo-respiratory exchange, and the lymphatic drainage system it is not surprising that there should be a group of diseases so commonly associated with pneumoconiosis as to be an essential part of its pathology—e.g., chronic bronchitis and emphysema, various types of cardiac failure, and the terminal bronchopneumonias. Pathologically these are, for the most part, naked eye diagnoses which do not come within the scope of this paper. Two others, however, are based on histological investigation—namely, tuberculosis and malignant disease. Tuberculosis has long been recognised as ætiologically important in pneumoconiosis, but it is only within recent years that a high incidence of primary pulmonary carcinoma has been suspected.

For pneumoconiosis of all forms, the incidence of 42·95% of tuberculosis in the present series may be compared with the figures for silicosis found by other investigators. Thus in a series of necropsies on sandstone workers, Meiklejohn (1949) found that 44·3% of those with silicosis had tuberculosis also whilst in pottery workers the percentage was 40. Merewether (1936) found that of 38 sandblasters who had died of silicosis 28 (73·7%) also had tuberculosis. The figure for this occupation in the present series is 69·6%. Sandblasting has now been abolished in this country in favour of the less harmful operation of shot blasting, for which mortality figures are not yet available.

No satisfactory control group has been found with which to compare the incidence (7·7%) of primary lung cancer in the 1036 cases of pneumoconiosis. In the 169 cases which proved not to be pneumoconiosis the incidence was 8·3%. In both groups, selection may have been exercised in picking out cases in which the radiographs and clinical histories had been unusual for an uncomplicated pneumoconiosis. Bradford Hill and Lewis Faning (1948), investigating the mortality in an arsenic factory, noted a proportional and significant excess of deaths attributed to cancer of all sites (and especially of the lung and skin) in the arsenic workers (29%), compared with the mortality of three other occupational groups living in the same area (13%).

The necropsy records for 1928–39 at the London Chest Hospital, where selection is obviously at work in picking out these cases for special observation and treatment, show the high incidence of 151 primary lung cancers (21·3%) in 706 necropsies, whereas at the other end of the scale the Registrar General (1950) reports for 1948 2·4% (3·9% of males and 0·9% of females) of the deaths from all causes in the general population over the age of 15 as being due to primary malignant disease of the lung (all forms). This last figure is an increase on those of previous years. Although comparable sets of statistics appear to be lacking, the evidence on all sides seems to point to an increase of deaths from primary cancer of the lung in the general population. It seems reasonable to suppose that workers with a dust hazard have their share in this increase. Whether they have a risk over and above this as a result of their occupation cannot yet be clearly shown, but the mortality of the asbestos workers is disturbing. In the present series 14% of the patients with asbestosis also had primary cancer of the lung. This is all the more striking because so many of them (41·2%) were females. This proportion of female deaths is greater than that in the general population, where the incidence of primary cancer of the lung is 4·4 males to 1 female.

The association of active pulmonary tuberculosis with cancer of the lung has been noted by several observers, both in general and in chest hospitals. Simpson (1929) found active tuberculosis in 4·2% of the necropsies on cases of primary pulmonary carcinoma at the London Hospital, Maxwell (1930) in 5·4% at the Royal Chest Hospital and St. Bartholomew's, Davidson (1930) in

6 5% at Brompton, and Gloyne in 6 4% at the London Chest Hospital, making an incidence of 5 5% of 648 necropsies in all the records In the present investigation, where pneumoconiosis is added, the incidence is still greater, there were 15 cases (18 7%) of tuberculosis in 80 cases of pneumoconiosis accompanied by primary carcinoma of the lung In view of the prevalence of tuberculosis in the population of this country it is not surprising that 5% of lung cancers at necropsy should reveal active tuberculosis, but it is not clear why this percentage should rise to four times that proportion when pneumoconiosis is present also At necropsy a lung which has three separate diseases in it is a much damaged organ, and it is not always possible to determine whether the tuberculosis is an exacerbation of an old lesion or a terminal infection In either case the obstruction to the lymphatic absorption produced by the pneumoconiosis and neoplasm together must be very considerable, and may well be a determining factor

The fact that in the pneumoconiosis series 21% of the cases of silicosis, 13 5% of those with tuberculosis, and *7 5% of those with carcinomata of the lungs were only* diagnosed on microscopical examination emphasises the rule (if such emphasis is needed) that a histological examination should never be omitted

Finally this record shows that the majority of the deaths took place in the age group 45–64—i e, in the prime of life, when experience in these skilled occupations counted most

SUMMARY

This paper summarises the findings in a consecutive series of 1247 lungs or portions thereof, examined microscopically for the presence of pneumoconiosis

Of these, 42 were deleted because of inadequate data Of the remainder, pneumoconiosis was not found in 169 but was present in 1036 (silicosis 796, other forms of pneumoconiosis 240) Of the positives, 43% had tuberculosis also, and 7 7% had primary cancer of the lung The histological features of the cases are discussed

Cordial acknowledgments are due for much help generously given by Dr E R A. Merewether and the medical staff of the Factory Department, Ministry of Labour, Dr C L Sutherland and his colleagues, of the Pneumoconiosis Medical Panel, Ministry of National Insurance, Dr K F W Hinson and the staff of the pathological department of the London Chest Hospital, Dr W T Russell and the staff of the statistical department of the Institute of Social Medicine, Oxford, Dr H Wyers, Dr E L Middleton, Dr A Meiklejohn, and the many pathologists who sent specimens

> "An artery had suddenly burst, and as Attila lay in a supine posture, he was suffocated by a torrent of blood, which instead of finding a passage through the nostril regurgitated into the lungs and stomach"—GIBBON's *Decline and Fall of the Roman Empire*, Chap xxxv

SINCE the adoption of early feeding and liberal transfusion in the routine treatment of bleeding peptic ulcer, it is generally assumed that the mortality from this illness has fallen to very low levels The results in expert hands seem to support this conclusion Avery Jones (1947), for example, had a fatality rate of 7 8% in his series Nevertheless, realisation is now more widespread that outside the special clinics such good results are less common (Lewin and Truelove 1949)

TABLE I—THE LESIONS AND MORTALITY

Lesions	Males			Females			Males and females		
	Total	Died	Mortality (%)	Total	Died	Mortality (%)	Total	Died	Mortality (%)
Chronic gastric ulcer	36	15	41 7	13	3	23	49	18	36 7
Chronic duodenal ulcer	37	5	13 5	11	—	—	48	5	10 4
Anastomotic ulcer	4	—	—	1	—	—	5	—	—
"Acute syndrome"	12	2	16 6	16	2	12 5	28	4	14 3
Not proven	12	1	8 3	11	—	—	23	1	4 3
Cirrhosis of liver	1	—	—	1	—	—	2	—	—
Gastric polyposis	—	—	—	1	—	—	1	—	—
Carcinoma of stomach	1	—	—	—	—	—	1	—	—

We report here our experience from January, 1947, to October, 1949, at a general hospital, formerly a separate municipal hospital, which has recently been reorganised as one wing of a larger unit under a regional board The patients were admitted into both medical and surgical wards, and were treated by a number of different physicians and surgeons, including ourselves

To assess accurately the incidence and mortality of bleeding peptic ulcer we scrutinised the notes of every admission during this period, whatever the official diagnosis Sometimes patients discharged as cases of gastric ulcer had been originally admitted with a hæmatemesis "Anæmia" might cloak a slowly progressing melæna Study of all the necropsy reports soon showed us that some bleeding ulcers had not been detected in life Patients with undetected bleeding ulcers have a high death rate and would rarely gain admission to special gastro enterological units Consequently the fatality rate in such units would err on the low side

TABLE II—AGE INCIDENCE AND MORTALITY

Age (yr)	Males			Females			Males and females

2	4	1	25	3	—	—	7	1	14
3	2	—	—	—	—	—	2	—	—
4	1	—	—	—	—	—	1	—	—
5	—	—	—	1	—	—	1	—	—

The remaining uncertainties were misdiagnosed patients who died without necropsy and the misdiagnosed who recovered despite lack of appropriate treatment

THE PRESENT SERIES

The patients were for the most part drawn from the surrounding neighbourhood and were artisans, labourers, factory workers, small shopkeepers, housewives, and old age pensioners Most belonged to the poorer classes

There were 157 admissions (103 males, 54 females) and 5 patients were admitted twice Although our object was to find out the mortality of hæmorrhage from peptic ulcer, it will be seen from table I that our series includes 1 ulcer which showed evidence of malignancy on histological examination, 1 patient with polyposis of the stomach, and 2 patients who probably had cirrhosis of the liver The rest of the patients fell into the categories of chronic gastric ulcer, chronic duodenal ulcer, anastomotic ulcer, "acute syndrome," or "not proven" (Peptic ulcers with occult blood on routine examinations were not included) Those labelled clearly gastric, duodenal, or anastomotic ulcer were patients in whom an ulcer was demonstrated radiologically, by gastroscopy, at operation or at necropsy The term "acute syndrome" covers those in whom an acute ulcer was seen, usually at necropsy, and those who gave a history suggesting an ulcer of less than four weeks' duration, although no lesion could be demonstrated "Not proven" was a term applied to patients who gave a history of longer than four weeks but in whom no ulcer was found The limit of four weeks is arbitrary, and perhaps it would be more scientific to lump most of the last two classes into the one of "not proven", nevertheless, it seems useful to try to assess the incidence and prognosis of bleeding in cases where acute ulceration is probable Since we were primarily concerned with the outlook in simple peptic ulcer, we have not included patients with obvious carcinoma of the stomach, although we have formed the impression that severe hæmorrhage rarely occurs in this disease

TABLE IV—LENGTH OF ULCER HISTORY AND MORTALITY

Duration	Patients under 50			Patients over 50		
	No	Died	Fatality rate (%)	No	Died	Fatality rate (%)
Less than 1 year	12	—	—	22	4	18·4
1–5 years	7	—	—	13	3	23 1
6–10 years	12	1	8 3	14	4	28 6
Over 10 years	13	1	7 7	31	6	19 4
No history	5	1	20	19	6	31 5
Years	2	—	—	7	2	28 5

Table I shows that 49 patients had chronic gastric ulcer, 48 chronic duodenal ulcer, 5 anastomotic ulcer, and 28 "acute syndrome," and 23 were "not proven"

To give as clear a picture as possible no death has been omitted There were 28 deaths in our total of 157 admissions for gastroduodenal bleeding, a mortality of 17 8% (table II) Even with the strictest criteria it would be permissible to exclude a man, aged 73, who had a very small hæmatemesis on admission but died of a perforation three months later There was also a man, aged 78, admitted for a perforated gastric ulcer, who bled terminally five days after operation As Avery Jones (1947) says "the additional hazard of the prior perforation renders comparison with other groups unreal" This still leaves 26 deaths in 156 admissions, a corrected fatality-rate of 16 6%

FACTORS IN MORTALITY

Age

We agree with other recent workers on the importance of age in determining the issue Of 51 patients under the age of 50, as can be seen from table II, only 3 died (5 9%) Or if 60 is taken as the threshold of old age, 9 died out of 84 (10 7%) Of the 106 patients over 50 years of age 25 died, a fatality rate of 23 6% In patients over the age of 50, mortality from hæmatemesis or melæna was nearly four times heavier than in patients under that age It is obvious that, in comparing different series, the age distribution must be known We had 73 patients over 60 years old (46 5%), compared with 33% in Avery Jones's (1947) series and 42% in Tanner's (1950) series

TABLE V—DISTRIBUTION OF CHRONIC GASTRIC AND DUODENAL ULCER IN PATIENTS UNDER AND OVER THE AGE OF 50

Age group	Males		Females	
	With gastric ulcer	With duodenal ulcer	With gastric ulcer	With duodenal ulcer
Under 50	8	12	3	2
Over 50	28	25	10	9

Sex

Table II shows a big difference in the incidence and mortality in the two sexes. There were nearly twice as many men as women, and whereas 23 of the men died (22 3%) *only* 5 women died (9 2%) This, too, agrees with the findings of other observers There was 1 death in a woman under the age of 50, 2 in women in the 70s, and 2 in women over the age of 80

Previous Ulcer History and Bleeding

A history of past ulcer bleeding in a patient with hæmatemesis and melæna does not make the prognosis worse As shown in table III, there is little difference in the fatality rate between those who have had no previous bleeding and those who have had one or two such episodes Some few patients with a history of three, four, or five past hæmorrhages have survived

The length of the ulcer history furnishes no guide in estimating the outlook for the patient with hæmorrhage (table IV) In our series those patients with no history of previous dyspepsia carried the highest fatality rate In the other categories age seemed to be a more important factor than the duration of the symptoms of peptic ulceration

Type of Lesion

The next inquiry concerned the type of lesion Table I reveals that the numbers of patients with gastric ulcer

TABLE VI—LOWEST AMOUNT OF HÆMOGLOBIN % (HALDANE) RECORDED

Lowest Hb recorded (Haldane)	No of patients	No of deaths
10–19	1	—

90–99	11	1
100 +	10	2
Not recorded	9	9

6 5% at Brompton, and Gloyne in 6 4% at the London Chest Hospital, making an incidence of 5 5% of 648 necropsies in all the records In the present investigation, where pneumoconiosis is added, the incidence is still greater, there were 15 cases (18 7%) of tuberculosis in 80 cases of pneumoconiosis accompanied by primary carcinoma of the lung In view of the prevalence of tuberculosis in the population of this country it is not surprising that 5% of lung cancers at necropsy should reveal active tuberculosis, but it is not clear why this percentage should rise to four times that proportion when pneumoconiosis is present also At necropsy a lung which has three separate diseases in it is a much damaged organ, and it is not always possible to determine whether the tuberculosis is an exacerbation of an old lesion or a terminal infection In either case the obstruction to the lymphatic absorption produced by the pneumoconiosis and neoplasm together must be very considerable, and may well be a determining factor

The fact that in the pneumoconiosis series 21% of the cases of silicosis, 13 5% of those with tuberculosis, and 7 5% of those with carcinomata of the lungs were only diagnosed on microscopical examination emphasises the rule (if such emphasis is needed) that a histological *examination should never be omitted*

Finally this record shows that the majority of the deaths took place in the age-group 45-64—i e, in the prime of life, when experience in these skilled occupations counted most

SUMMARY

This paper summarises the findings in a consecutive series of 1247 lungs or portions thereof, examined microscopically for the presence of pneumoconiosis

Of these, 42 were deleted because of inadequate data Of the remainder, pneumoconiosis was not found in 169 but was present in 1036 (silicosis 796, other forms of pneumoconiosis 240) Of the positives, 43% had *tuberculosis also, and 7 7% had primary cancer of* the lung The histological features of the cases are discussed

Cordial acknowledgments are due for much help generously given by Dr E R A Merewether and the medical staff of the Factory Department, Ministry of Labour, Dr C L Sutherland and his colleagues, of the Pneumoconiosis Medical Panel, Ministry of National Insurance, Dr K F W Hinson and the staff of the pathological department of the London Chest Hospital, Dr W T Russell and the staff of the statistical department of the Institute of Social Medicine, Oxford, Dr H Wyers, Dr E L Middleton, Dr A. Meiklejohn, and the many pathologists who sent specimens

> "An artery had suddenly burst, and as Attila lay in a supine posture, he was suffocated by a torrent of blood, which instead of finding a passage through the nostril regurgitated into the lungs and stomach"—GIBBON'S *Decline and Fall of the Roman Empire*, Chap xxxv

SINCE the adoption of early feeding and liberal transfusion in the routine treatment of bleeding peptic ulcer, it is generally *assumed that the mortality from this* illness has fallen to very low levels. The results in expert hands seem to support this conclusion Avery Jones (1947), for example, had a fatality rate of 7 8% in his series Nevertheless, realisation is now more widespread that outside the special clinics such good *results are less common (Lewin and Truelove 1949)*

Carcinoma of stomach	1	—	—	—	—	—	1	—	—

We report here our experience from January, 1947, to October, 1949, at a general hospital, formerly a separate municipal hospital, which has recently been reorganised as one wing of a larger unit under a regional board The patients were admitted into both medical and surgical wards, and were treated by a number of different physicians and surgeons, including ourselves

To assess accurately the incidence and mortality of bleeding peptic ulcer we scrutinised the notes of every admission during this period, whatever the official *diagnosis Sometimes patients* discharged as cases of gastric ulcer had been originally admitted with a hæmatemesis "Anæmia" might cloak a slowly progressing melæna Study of all the necropsy reports soon showed us that some bleeding ulcers had not been detected in life Patients with undetected bleeding ulcers have a high death rate and would rarely gain admission to special gastro enterological units Consequently the fatality rate in such units would err on the low side.

D U = chronic duodenal ulcer
R = recovered
D = died

formed, but death ensued from general peritonitis A third patient who underwent emergency gastrectomy died on the table, at necropsy it was found that a purulent bronchitis filled the air passages with pus Another patient died of peritonitis following a “ cold ” gastrectomy undertaken four weeks after hæmatemesis. In the sixth patient gastric bleeding occurred a few days after operation for perforation

In 2 patients the bleeding seems to have played only a minor part in determining the outcome One feeble old man perforated three months after a small hæmatemesis, and a second died of chronic bronchitis and heart-failure nine weeks after his melæna An old lady recovered from her hæmatemesis sufficiently to become ambulant, but four weeks later she died suddenly of cardiac infarction

TABLE X—DISTRIBUTION OF LESIONS IN PATIENTS WITH SEVERE INTERCURRENT DISEASE

Type of lesion	Males		Females	
	No died	No recovered	No died	No recovered
Acute syndrome	1	0	2	0
Chronic gastric ulcer	8	3	1	0
Chronic duodenal ulcer	2	3	—	—
Not proven	1	5	0	3
Total	12	11	3	3

6 patients had no adequate treatment because their true condition was undiagnosed in life This point is discussed below

In 4 men the bleeding was so rapid and massive that they were moribund before treatment could even be initiated 1 died three minutes after admission, one two hours after Another was admitted for investigation and had an overwhelming terminal hæmorrhage, at necropsy there was a 2 pint clot in the stomach—an artery in the pancreas had eroded In the fourth case death took place twelve hours after admission, an acute ulcer had eroded the splenic artery, and the stomach contained a 2½ pint clot

Severe complicating disease was a prominent feature of other fatal cases 2 patients, for example, had fibrocaseous tuberculosis with cavitation, and another had an advanced carcinoma of the pancreas

1 man, a debilitated alcoholic, recovered from an initial hæmorrhage Gastrectomy was to be done when he should be well enough, but a fatal hæmorrhage took place before the ideal state could be reached

2 men might have been saved by timely operation a man of 64 who died from paralytic ileus after eight days' continual hæmorrhage, and a man of 52 who perforated forty eight hours after admission The 3 remaining fatalities were in a man of 70 who had a localised perforation of his duodenal ulcer, bronchopneumonia, and cirrhosis of the liver, a man of 67, with two chronic gastric ulcers, who had a severe terminal hæmorrhage (he had also a small carcinoma of the lung), and a man of 55 with a complicating bronchopneumonia The 2 last were possibly amenable to surgery at an earlier stage

SEVERE INTERCURRENT DISEASE

As might be expected from the high proportion of old people in this series, intercurrent disease was common Excluding hypertension and atheromatous changes unless there were cardiac and cerebral involvement, complicating diseases were prominent in 29 patients (table IX) There were 6 women, of whom 3 died, and 23 men, of whom 12 died All but 1 of these patients were over the age of 50 The distribution according to the type of peptic ulcer is shown in table X, it will be seen that there were 12 patients with chronic gastric ulcer, and 9 of them died

TABLE XI—FATALITY RATES IN PATIENTS UNDER AND OVER THE AGE OF 50

Age group	Males			Females			Total		
	No of patients	Died	Fatality rate (%)	No of patients	Died	Fatality rate (%)	No of patients	Died	Fatality rate (%)
Under 50	36	2	5 6	15	1	6 7	51	3	5 9
Over 50	67	21	31 3	39	4	10 3	106	25	23 6

Our next consideration was the part played by severe intercurrent disease in causing the great difference in mortality between those under and those over the age of 50 In table XI the fatality rate in males under the age of 50 is 5 6%, whereas over that age it is 31 3%, this difference is significant If patients without severe intercurrent disease are analysed (table XII), we see that the fatality rate in men under the age of 50 was 5 7%, and in men over that age 20% It is doubtful whether this is statistically significant Too much emphasis should not be laid on these figures, which are comparatively small, but it is at any rate suggestive that the increasing mortality with age in bleeding peptic ulcer may be associated with the increasing frequency of severe complicating disease

TABLE XII—FATALITY-RATE IN PATIENTS WITHOUT SEVERE INTERCURRENT DISEASE UNDER AND OVER THE AGE OF 50

Age group	Males			Females			Total		
	No of patients	Died	Fatality rate (%)	No of patients	Died	Fatality rate (%)	No of patients	Died	Fatality rate (%)

8	3	—	3
9	—	1	1
15	1	—	1
23	1	—	1

73 of the patients were transfused 306 bottles were used averaging about 4 bottles per patient transfused 1 bottle = 540 ml of blood

and duodenal ulcer were almost equal In men under the age of 50 there were more instances of chronic duodenal ulcer than of chronic gastric ulcer, but the difference is not significant (table v) Nevertheless the deaths from bleeding gastric ulcer were about three and a half times as numerous as those from duodenal ulcer This difference applied to women as well as men Of interest too is the high death rate in the "acute syndrome"—4 out of 28 patients (14 3%) Ulceration was demonstrated in 105 patients (67%) or about two thirds of our series

BLOOD LOST AND AMOUNT TRANSFUSED

To assess the value of treatment, some idea is necessary of the severity of the bleeding Many patients with slight loss of blood would recover, whatever the treatment It is not always easy to judge the clinical condition from a perusal of the notes As rough guides we tabulated the lowest amount of hæmoglobin recorded and the volume of blood transfused These guides may be misleading Sometimes a large terminal hæmorrhage occurred in a patient who had previously bled only slightly and whose lowest recorded amount of hæmoglobin was 90% (Haldane) On the other hand, some patients bled slowly and steadily for several weeks and readjusted themselves to a hæmoglobin level surprisingly low

The amount of blood transfused (table VII) in a particular instance depended to some extent on the predilection and training of the doctor as well as on the amount of blood lost The tendency was to transfuse early rather than late In the more recent admissions the object was to make the patient fit enough to stand a possible recurrence of hæmorrhage or an emergency operation Of the 73 patients transfused, few received more than six bottles (each bottle contained 540 ml of blood)

At least one patient died so quickly that no blood could be given in time In another case twenty three bottles were given for a succession of severe hæmorrhages In Rh negative patients a difficulty was to obtain sufficient compatible blood, and this caused us to prefer early operation to prolonged transfusion in these cases

The amount of hæmoglobin was recorded in 148 patients As is well known, in those who have recently bled the hæmoglobin may remain high before hæmodilution takes place In those who have bled repeatedly the level of hæmoglobin may be high because of hæmoconcentration Table VI shows that the hæmoglobin was less than 40% (Haldane) in 40 patients (27%), it was over 80% in 31 (20 9%) There were 10 deaths in the former group In another 9 fatal cases no record of the hæmoglobin could be found Most of these cases had not been diagnosed in life and were traced through the necropsy records This increases the difficulty of correlating the degree of anæmia with the fatality rate

THE DEATHS

Much thought has been given to the 28 fatalities to discover where treatment may have erred We have summarised the findings in every patient who died (table VIII) There were 18 deaths from chronic gastric ulcer, 5 from chronic duodenal ulcer, 4 from acute ulcer, and 1 from a clinical but not proved duodenal ulcer Of these patients 6 had had an operation In 1 the ulcer was undersewn, but the man bled again ten days later In 2 others emergency gastrectomy was per

TABLE VIII—SUMMARY OF FATAL CASES

No	Age	Sex	Clinical notes
1	73	F	Acute syndrome Died of cardiac infarction a month after admission
2	69	M	G U Hæmatemesis Treated conservatively Improved Second hæmatemesis 6 weeks later Ulcer undersewn within 24 hours. Died of further bleeding 10 days after Chronic bronchitis
3	69	M	G U Partial gastrectomy 5 days after admission Died 3 days later of general peritonitis
4	64	M	D U Transfusions only Died after 8 days—paralytic ileus
5	52	M	G U Perforated on second day Died after 8 days
6	53	M	Overwhelming hæmorrhage 12 hours after admission. Necropsy acute ulcer with erosion of splenic artery, hypertension, cardiac involvement
7	73	M	D U Small hæmatemesis Died after perforation 3 months later
8	61	M	G U and acute ulcer Severe hæmorrhage 4 days after admission Emergency gastrectomy 5 days later but died on the table
9	44	F	G U with hour glass stomach Bled while in hospital for investigation Emergency gastrectomy Died of peritonitis
10	58	M	D U Transfused but relapsed Necropsy bronchopneumonia, active tuberculosis with cavitation
11	56	M	G U Undiagnosed Untreated Cardiac failure

Total	12	11	3	3

6 patients had no adequate treatment because their true condition was undiagnosed in life. This point is discussed below.

In 4 men the bleeding was so rapid and massive that they were moribund before treatment could even be initiated. 1 died three minutes after admission, one two hours after. Another was admitted for investigation and had an overwhelming terminal hæmorrhage; at necropsy there was a 2 pint clot in the stomach—an artery in the pancreas had eroded. In the fourth case death took place twelve hours after admission; an acute ulcer had eroded the splenic artery, and the stomach contained a 2½ pint clot.

Severe complicating disease was a prominent feature of other fatal cases. 2 patients, for example, had fibrocaseous tuberculosis with cavitation, and another had an advanced carcinoma of the pancreas.

1 man, a debilitated alcoholic, recovered from an initial hæmorrhage. Gastrectomy was to be done when he should be well enough, but a fatal hæmorrhage took place before the ideal state could be reached.

2 men might have been saved by timely operation: a man of 64 who died from paralytic ileus after eight days' continual hæmorrhage, and a man of 52 who perforated forty-eight hours after admission. The 3 remaining fatalities were in a man of 70 who had a localised perforation of his duodenal ulcer, bronchopneumonia, and cirrhosis of the liver; a man of 67, with two chronic gastric ulcers, who had a severe terminal hæmorrhage (he had also a small carcinoma of the lung); and a man of 55 with a complicating bronchopneumonia. The 2 last were possibly amenable to surgery at an earlier stage.

SEVERE INTERCURRENT DISEASE

As might be expected from the high proportion of old people in this series, intercurrent disease was common. Excluding hypertension and atheromatous changes unless there were cardiac and cerebral involvement, complicating diseases were prominent in 29 patients (table IX). There were 6 women, of whom 3 died, and 23 men, of whom 12 died. All but 1 of these patients were over the age of 50. The distribution according to the type of peptic ulcer is shown in table X; it will be seen that there were 12 patients with chronic gastric ulcer, and 9 of them died.

TABLE XI—FATALITY-RATES IN PATIENTS UNDER AND OVER THE AGE OF 50

Age group	Males			Females			Total		
	No of patients	Died	Fatality rate (%)	No of patients	Died	Fatality rate (%)	No of patients	Died	Fatality rate (%)
Under 50	36	2	5·6	15	1	6·7	51	3	5·9
Over 50	67	21	31·3	39	4	10·3	106	25	23·6

Our next consideration was the part played by severe intercurrent disease in causing the great difference in mortality between those under and those over the age of 50. In table XI the fatality-rate in males under the age of 50 is 5·6%, whereas over that age it is 31·3%; this difference is significant. If patients without severe intercurrent disease are analysed (table XII), we see that the fatality rate in men under the age of 50 was 5·7%, and in men over that age 20%. It is doubtful whether this is statistically significant. Too much emphasis should not be laid on these figures, which are comparatively small, but it is at any rate suggestive that the increasing mortality with age in bleeding peptic ulcer may be associated with the increasing frequency of severe complicating disease.

TABLE XII—FATALITY-RATE IN PATIENTS WITHOUT SEVERE INTERCURRENT DISEASE UNDER AND OVER THE AGE OF 50

Age-group	Males			Females			Total		
	No of patients	Died	Fatality rate (%)	No of patients	Died	Fatality rate (%)	No of patients	Died	Fatality rate (%)
Under 50	35	2	5·7	15	1	6·7	50	3	6·0
Over 50	45	9	20·0	33	1	3·0	78	10	12·8

DIAGNOSIS

Mention has already been made of 6 patients in whom the diagnosis was made only at necropsy Except for a man of 55, they were all well stricken in years (71, 78, 85, and 87) In another 5 patients the diagnosis was missed at first It must be remembered that bleeding peptic ulcer is not always dramatic, and that in the old, the sick, the *anæmic, and the demented* memory is vague and history obscure Care and great patience are required to enable one to reach the diagnosis before the pathologist does For example

A man of 56 was referred to medical outpatients as a case of cardiac dyspnœa It was found that six days previously he had had a brisk hæmorrhage from an acute ulcer and his hæmoglobin was 50% (Haldane)

A man of 56 was admitted as a case of bronchopneumonia His hæmoglobin was 22% (Haldane) and he had pulmonary œdema

A man of 78 was admitted with hæmoglobin 22% (Haldane) and normal stools He was thought to have pernicious anæmia, until a fatal hæmorrhage gave the answer

Such experience has caused us to view with suspicion any anæmia of recent onset, even though there is no clear gastric history In these circumstances a rectal examination may reveal melæna

SURGERY

Of the 31 patients treated surgically, 5 died, a mortality of 16% 20 of these were "cold" gastrectomies, with 1 death (5% mortality), and the remaining 11 had emergency operations leading to 4 deaths (36%) 21 of those operated on had gastric ulcer, 8 duodenal ulcer, 1 anastomotic ulcer, and 1 gastric polyposis All 5 deaths took place in those with gastric ulcer The *patient with hæmorrhage after perforation* is not included

Among the 15 patients under the age of 50 there were 5 emergency operations with 1 death, and 10 "cold" operations with no deaths Among the 16 over the age of 50 there were 6 emergency operations with 3 deaths and 10 "cold" operations with none The numbers are small but emergency operation in patients over the age of 50 seems to be hazardous It must, however, be admitted that these patients were operated on at various times after the hæmorrhage had begun and were usually gravely ill

Gastrectomy done in selected cases after bleeding has ceased is safe even in the elderly

DISCUSSION

The burning question in the treatment of bleeding ulcer *at present is the rôle of surgery* Excellent results have been achieved by those with a medical bias, such as Avery Jones, and equally good results by those with a surgical bias, such as Tanner In our study we have sought guiding generalisations and like other observers we have found that the prognosis is worse in the elderly, in men, and in those with gastric ulcer A history of previous bleeding, or of symptoms over a long period, affects the outcome but little Before treatment, diagnosis is necessary, and it was disquieting to find that in 6 cases no diagnosis had been made in life In others the diagnosis was late Elderly people with chronic peptic ulceration who have been bleeding for a long time are often cachectic to a degree that suggests advanced malignant disease It would be a grave error to withhold energetic treatment on the mistaken supposition that the prognosis is hopeless

We have tried to find a reason for the higher *fatality-rates* in the older patients One possibility would be an increasing proportion of the more lethal chronic gastric ulcer in older people, but in our series the difference in distribution of chronic gastric and duodenal ulcer below and above the age of 50 is not significant A second possibility is that severe intercurrent disease is more likely to be present in the elderly This seems to us a very important factor and is too often overlooked

The treatment of the present patients was usually medical in the first instance, but if this appeared to be failing, surgery was undertaken at the earliest possible moment This was the practice both of physicians and surgeons, although it is likely that the surgeons would the sooner recognise the failure of medical methods With early and close cooperation of physician and surgeon the charge that patients are left too late for surgery can be avoided Confronted with a bleeding patient the doctor must decide whether medical measures alone will stop the hæmorrhage or whether surgery must be invoked without delay As Lewison (1950) succinctly puts it, the problem is "to differentiate by as precise a means as possible which cases cannot be controlled short of surgery" Statistics and laboratory tests here are little help The exceptions are too many From the study of the patients who died we are not convinced that immediate routine surgery would save more lives than would careful selection In our 28 fatal cases we think it possible that 3 or 4 patients would have had a better chance if treated surgically We doubt whether much more could have been done for the others This would still leave a mortality of about 14–15% In the end all rests on the experience and judgment of the clinician and on the surgical facilities to hand

SUMMARY

157 consecutive admissions for gastroduodenal bleeding are reviewed There were 28 deaths, a fatality rate of 17 8%

The prognosis was worse in men, in those over the age of 50, and in those with chronic gastric ulcers Severe complicating disease and failure of correct diagnosis affect the prognosis adversely in the elderly

There is no *rigid formula enabling one to detect the* cases that will respond only to surgery Surgical treatment should be based on careful selection of patients *and close cooperation of physician and surgeon*

We wish to thank our colleagues for their very helpful criticism, in particular Dr F Binks, Mr W Davey, Dr A. L Jacobs, and the late Mr I I Price

STILBŒSTROL SULPHATE, ŒSTRONE, AND EQUILIN

FURTHER OBSERVATIONS ON THE POTENCY AND CLINICAL ASSESSMENT OF ŒSTROGENS

P M F Bishop
D M Oxfd
ENDOCRINOLOGIST TO GUY'S HOSPITAL AND CHELSEA HOSPITAL FOR WOMEN, AND DEPARTMENT OF OBSTETRICS AND GYNÆCOLOGY, POSTGRADUATE MEDICAL SCHOOL OF LONDON

MEMBER OF STAFF, MEDICAL RESEARCH COUNCIL

In *previous studies* the potencies of the synthetic œstrogens stilbœstrol, dienœstrol, hexœstrol, and bis dehydrodoisynolic acid (Bishop et al 1948) and of the compounds ethinyl œstradiol and equine conjugated œstrogen (Bishop et al 1950) were compared by observing their action in the production of uterine bleeding in women with amenorrhœa

"Equine conjugated œstrogen" denotes the extract f œstrogenic substances from the urine of pregnant mares The extract is prepared by collecting urine rom pregnant mares kept in stables during the winter The urine is immediately cooled to low temperatures by tanding the collecting barrels out of doors The resulting extract is a mixture of conjugated œstrogens, containng among other compounds œstrone sulphate. Equine conjugated œstrogen proved to be almost half as potent as stilbœstrol and therefore probably considerably more potent than œstrone

Accordingly it seemed desirable to study the potencies of the sulphates of the stilbene group of synthetic œstrogens, so as to determine whether these salts were also more potent than their corresponding œstrogens It soon became clear that they were not going to prove to be so, and consequently further studies of dienœstrol sulphate and hexœstrol sulphate were abandoned Work on stilbœstrol sulphate was nevertheless continued and the results are recorded here

At the same time we were provided with supplies of pure œstrone and pure equilin by Dr H F Hailman, of the Upjohn Company, Kalamazoo, U S.A, and were therefore able to compare the potency of these two natural œstrogens with that of stilbœstrol

METHOD

The method of clinical assessment was the same as in the previous study, and the following description is quoted from Bishop et al. (1948)

> The œstrogen was given by mouth in daily doses for a fortnight to induce 'withdrawal bleeding' within fourteen days of the last dose, the usual interval being from two to four days The first course consisted of a 'sighting dose (usually 2 mg daily in the case of stilbœstrol) Depending on whether the response was positive or negative, the daily dose of the second course (the first bracketing' dose) was either lowered or raised—usually halved or doubled The daily dose of the third course (the second bracketing dose) was similarly adjusted according to the response of the first bracketing dose In this way a therapeutic unit was obtained being the mean of the daily doses of two courses one of which consisted of the highest and the other of the lowest, daily dose to fail or succeed, respectively to produce a withdrawal bleeding
>
> 'The patients selected had primary amenorrhœa or secondary amenorrhœa of at least some months' standing
>
> In general an attempt was made first to determine the therapeutic unit of stilbœstrol, and subsequently the therapeutic unit of one or more of the other œstrogens, on the same patient"

RESULTS

Of the 29 patients studied, 26 had secondary amenorrhœa and 3 primary amenorrhœa, 236 courses of œstrogen were given, 29 therapeutic units of stilbœstrol, 15 of stilbœstrol sulphate, 14 of œstrone, and 17 of equilin were obtained.

The statistical analysis was made in the same way as that previously used by Dr C W Emmens (Bishop et al. 1948) The logarithm of the ratio of the effective doses of two of the œstrogens on an individual patient was taken as the statistical unit The potencies and limits of error thus reached are shown in table I the comparisons being made with the therapeutic unit of stilbœstrol expressed as unity.

TABLE I

Substance	No of comparisons	Potency	Fiducial limits of error (P = 0·05)
Stilbœstrol sulphate	15	0·44235	0·27505–0·71145 (62·2–160·82 %)
Œstrone	14	0·04668	0·027632–0·075332 (59·2–168·9 %)
Equilin	17	0·32857	0·19546–0·42154 (68·6–145·7 %)

As in the previous trials (Bishop et al. 1950) the logarithms of the actual effective doses were subjected to analysis of variance (table II)

TABLE II

Œstrogens compared	Degree of freedom	Sum of squares	Mean ratio	F	P
Stilbœstrol v. stilbœstrol sulphate					
Between substances	1	1·00703	1·00703	10·341	< 0·01
Within substances	28	2·72653	0·09738		
Total	29	3·73356			
Stilbœstrol v œstrone					
Between substances	1	12·39882	12·39882	66·00	< 0·001
Within substances	26	4·88439	0·18786		
Total	27	17·28321			
Stilbœstrol v equilin					
Between substances	1	1·64939	1·64939	14·5719	< 0·001
Within substances	34	3·84857	0·11319		
Total	35	5·49796			

Potency ratios	*Potency*	*Fiducial limits of error* (P = 0·05)
Stilbœstrol sulphate v stilbœstrol	0·4301	0·2941–0·6289 (68·4–146 %)
Stilbœstrol v œstrone	0·04665	0·0270–0·0808 (57·8–173 %)
Stilbœstrol v equilin	0·37340	0·2572–0·5421 (68·9–145 %)

It will be seen that, as in the previous trial (Bishop et al. 1948), the potency worked out on this basis very closely resembles that calculated by the original method (table I)

TOXICITY

No toxic effects were encountered within the range of doses of stilbœstrol sulphate, œstrone, or equilin used in these trials.

DISCUSSION

Choice of End-point

In the previous report (Bishop et al 1948) reasons were given for our choice of œstrogen withdrawal bleeding in cases of amenorrhœa as the most suitable end-point for a clinical assessment of œstrogenic potency These reasons may be briefly recapitulated here

Other possible end points are relief of menopausal symptoms conversion of an atrophic to an œstrous type of vaginal smear and suppression of lactation

Relief of Menopausal Symptoms—These symptoms are entirely subjective and difficult to assess quantitatively Even if the daily hot-flush count were accepted as a semi-quantitative end point, considerable alterations in the count would have to occur to be significant, and after each course of œstrogen which gave a positive result the hot-flush count would have to be allowed to return to its pre-treatment base-line At least two œstrogens would have to be tested on each patient The assessment might therefore take many months during which the œstrogenic status of the patient might be constantly changing Finally the patient would be disinclined to endure the series of relapses which the return to the base line after each course of effective œstrogen therapy would entail

Changes in Vaginal Smear—We have seldom found menopausal women with a sufficiently labile smear to change from the atrophic to the œstrous condition and vice versa quickly enough to allow assessment of at least two œstrogens by this method

Suppression of Lactation—Only one course of œstrogen is given to succeed or fail to suppress lactation in any one patient on one occasion. It is therefore impossible to compare two œstrogens in the same patient

There are variables in the present method which might have been expected to vitiate the results seriously—

TABLE III—RELATIVE POTENCY (COMPARED WITH STILBŒSTROL) OF ŒSTROGENS ADMINISTERED ORALLY IN RATS AND THE HUMAN SPECIES

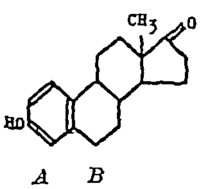
Œstrogen	Rat	Man
Stilbœstrol	100	100
Dienœstrol	68	26
Hexœstrol	10	5
Bis dehydrodoisynolic acid	500	21
Ethinyl œstradiol	18	2567
Equine conjugated œstrogen	5	49
Stilbœstrol sulphate (Broom 1951)	50	44
Œstrone	2	5

e g, the possibility of occasional spontaneous periods being mistaken for withdrawal bleedings, and the level of response in any one patient varying during the investigation That such variables did not in fact seriously affect the results seems clear from the statistical analysis

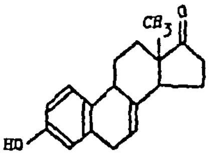
Comparison of Clinical Assessment and Animal Assay

Harmer and Broom (1948, 1950) and Broom (1951) have made large scale experiments to assess, by means of the changes in the vaginal smears, the activity of certain œstrogens given by mouth to ovariectomised adult rats Their results, set side by side with ours, show considerable, and in some instances fundamental, differences (table III) For instance, the two results agree in showing that stilbœstrol is more potent than dienœstrol, hexœstrol, equine conjugated œstrogen, stilbœstrol sulphate, and œstrone, ethinyl œstradiol is twenty-five times as potent as stilbœstrol in man, and only one fifth as potent in the rat, and bis dehydrodoisynolic acid is five times as potent in the rat and only a fifth as potent in man Among the œstrogens compared here it is interesting to note that stilbœstrol sulphate bears almost exactly the same ratio to stilbœstrol in man as it does in the rat, whereas œstrone is only a fiftieth as potent in the rat, though it is a twentieth as potent in man

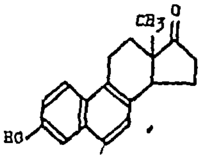
It was somewhat of a surprise to find equilin to be such an active œstrogen It was known that the activity of natural œstrogens is lowered when ring B of the steroid nucleus is aromatic as in equilenin Miescher 1948) The presence of a double bond at C7 in ring B, as in equilin, is said to have no effect on the œstrogenic activity (Miescher 1948), but the activity, as estimated by the vaginal smear, is stated to be only a quarter that of œstrone, and by the immature mouse uterine weight method only about a tenth (Pearlman 1948) Broom has not yet determined the oral potency of equilin by his method In view of the high activity of equilin as compared with œstrone found in the present study, it would be interesting to know whether the introduction of an ethinyl side chain at C17 would increase the oral potency of equilin as it does that of œstradiol The potency of ethinyl equilin is now being compared by us with that of stilbœstrol.



Œstrone



Equilin



Equilenin

SUMMARY

A method is described for comparing the potency of œstrogens in man It consists in giving the œstrogen daily by mouth in fourteen day courses to amenorrhœic women and recording whether œstrogen-withdrawal bleeding takes place

The results obtained indicate that stilbœstrol sulphate is half as potent as stilbœstrol, œstrone one twentieth as potent, and equilin one third as potent

"Toxicity" manifested as nausea was not encountered with these three œstrogens in the range of doses administered

Reasons are given for choosing this end point and for the failure to devise any other suitable method of assessment at different levels of œstrogenic response, such as relief of menopausal symptoms, the production of an œstrous vaginal smear, or the suppression of lactation

We wish to thank Sir Jack Drummond, F.R S, for facilities to enable us to carry out this work, and Dr H F Hailman for generous supplies of œstrone and equilin The stilbœstrol sulphate, dienœstrol sulphate, and hexœstrol sulphate were supplied by Boots Pure Drug Co Ltd and the œstrone and equilin by the Upjohn Corporation, of Kalamazoo, Michigan, U S A

THE SERUM-PROTEIN LEVELS OF SAMOANS, FIJIANS, AND INDIANS IN FIJI

LUCY WILLS
M A Camb, M B Lond

MURIEL E BELL
M.D N Z, F.N.Z.I.C.

From the Department of Nutrition Research Otago Medical School, Dunedin, New Zealand

DURING nutritional surveys in Fiji and Samoa the serum protein was estimated in 823 persons (Fijian and Indian) in Fiji, and 249 persons (all Samoans) in Samoa As the results show a marked deviation from the average findings reported for Europeans and for Indians in India, they are recorded in this note

MATERIAL AND METHODS

Those examined were as far as possible representative of the three races and of all age groups. The surveys were done in 1950, in January and February, which are wet months, it was therefore impossible to get into the remote inland districts in Fiji Groups of people were, however, examined in the principal towns and in the villages of the coastal zones in the islands of Viti Levu (Fiji) and of Upolu (Samoa), and in a large group of inland villages on the transisland road in Viti Levu A group of European hospital sisters and N Z R A F personnel who had been some time in Fiji were examined also

The total serum protein was determined by the copper sulphate specific gravity method of Phillips, Van Slyke et al (1945), with the use of Hoch and Marrack's (1945) formula, $P = 364\ (Gs - 1\ 0060)$ for calculating the percentage of protein The majority of the determinations were done on capillary blood The reliability of the method was checked by duplicate estimations on capillary and venous blood, the results showed close agreement The estimations were done as soon as possible after the blood had been taken, but a delay of 3–4 hours did not affect the values The results in the different groups are strictly comparable. Some samples of serum were flown to Dr Hans Hoch in America, who most kindly determined the total content of protein by estimating the specific gravity by direct weighing and also made electrophoretic analysis

TABLE I—MEAN SERUM-PROTEIN VALUES FOR DIFFERENT RACES IN FIJI AND SAMOA AT DIFFERENT AGES

Racial groups	Under 2 yr			2–5 yr			6–14 yr			15–30 yr			Over 30 yr

Europeans in Fiji				–						19	7 30 ±0 06	0 28			
Europeans in Samoa										1	7 10				

RESULTS

The results have been classified by race, age, and condition and the figures are shown in tables I and II There was no significant difference between the values obtained for men and women so these have been grouped together under their appropriate age group If the findings in pregnant women are excluded the figures show that by the age of 6–14 years the mean serum protein values for all the coloured races were significantly raised above the levels usual in Europeans and above those found in the present survey in people of European race living in Fiji In Samoan children the rise had already appeared by the age of 2–5 years, when the mean value was 7 96 ± 0 09 g per 100 ml compared with an expected figure of about 7 0 g per 100 ml All three races showed the same tendency, but in all age groups the mean values in Samoans were significantly higher than in the other two races, individual figures as high as 9 0 g per 100 ml and over being not uncommon in all age groups over 2 years In all three racial groups there was a slight fall in the protein level after the age of 30 years

The results obtained by electrophoresis by Dr Hoch for a sample of serum from a healthy young Fijian male are shown in table III The total protein value of 7 9 g per 100 ml agrees with our finding for this case The combined value for albumin and α globulin is within normal limits, though the percentage is low on account of the high γ globulin value which is about twice the normal figure The amount of β globulin is slightly reduced, both absolutely and relatively

The values obtained during pregnancy were considerably lower than the mean figure for other adults, the fall in all three race groups being by approximately 1 0 g per 100 ml by the third trimester, a fall of a similar order to that found by Hoch and Marrack (1948) and Macarthur (1948) and other workers, in European women during pregnancy

DISCUSSION

The raised total serum protein values found in apparently healthy individuals among Fijians, Indians in Fiji, and Samoans are in strong contrast with the levels reported for the European race, including members of it living in Fiji, and for Indians living in India The usually accepted mean level for normal adult Europeans, Indians, and Chinese of both sexes is about 7 0 g per 100 ml (Marrack and Hoch 1949, Havens and Williams 1948, Seibert et al. 1947, Hynes and Lehmann 1946, Walters et al 1947, Yi et al. 1948), though Datta and Chakravarty (1947) found a mean value of 7 5 g per 100 ml for healthy adult Indians of both sexes In our own small series from Fiji the figure for Europeans was 7 3 ± 0 06 g per 100 ml, a value significantly lower than those found in the other races after the age of 5–9 years

Similar high serum protein values have been reported in other races In West Africa Stephen (1948) made an extensive study of different groups of Africans, using the copper sulphate specific gravity method to determine the protein levels He found a progressive fall in the protein values from one of 7 8 g per 100 ml in a Service group with 6 weeks' service, through one of 7 4 g for a group with from 6–8 months' service, to a figure of 7 2 g for men with 2 or more years' service, much spent in India on European scale rations Adult male villagers had a mean value of 7 5 g per 100 ml In contrast with these findings the mean value for a group of 50 European soldiers stationed at Accra for from 3 to 18 months was only 6 9 g per 100 ml It should be noted that all these values would be about 0 4 g higher if Hoch and Marrack's formula had been used to calculate them instead of Phillips and Van Slyke's, the values would then agree very closely with the ones we obtained for the three coloured races and for Europeans in Fiji In two villages in Gambia Barakat and Smith (1949) found in the adult population a mean serum protein level of 7 7 g per 100 ml, there was clinical evidence in both villages of deficiencies in total calories and in the vitamin B complex Mohun (1946) reported a similar but smaller increase in the mean protein value in a small group of young African Servicemen Similarly, Milam (1946) found that negroes in North Carolina had a higher mean serum protein value than whites in the same district and that the increase was due to a raised globulin value, associated in this case, however, with a decreased

TABLE III—DISTRIBUTION OF PROTEIN FRACTIONS IN THE BLOOD SERUM OF A HEALTHY YOUNG MALE FIJIAN, COMPARED WITH THE NORMAL VALUES

(Dr Hans Hoch s Figures)

Protein fraction	Amount (g /100 ml)		Fraction of total protein %	
	Fijian	Normal	Fijian	Normal
Albumin and globulin	4 2	4 5	53 0	61·6
α_1 globulin	0 75	0 75	9 5	10·4
β-globulin	0 65	1 00	8 5	13 8
γ-globulin	2 3	1 05	29 0	14 2
Total proteins	7 9	7 3	100 0	

TABLE II—MEAN SERUM PROTEIN VALUES IN PREGNANT WOMEN OF DIFFERENT RACES IN FIJI AND SAMOA AT DIFFERENT STAGES OF PREGNANCY

Racial groups	At 1–40 wks			At 1–16 wks			At 17–28 wks			At 29–40 wks		
	No	Serum protein		No	Serum protein		No	Serum protein		No	Serum protein	
		g /100 ml	SD		g /100 ml	SD		g /100 ml	SD		g /100 ml	SD
Samoans	32	7 46 ±0 10	0 53	9	7 72 ±0 18	0 53	16	7 46 ±0 08	0 31	7	7 13 ±0 31	0 83

Indians	88	6 97 ±0 04	0 36	11	7 16 ±0 15	0 51	40	7 01 ±0 04	0 29	37	6 88 ±0 06	0 39

albumin value But high serum protein values are not a racial characteristic of the African Quinton and Barnes (1942) in Johannesburg, using the biuret method, found an average figure of 7 3 g per 100 ml in a group of 68 healthy Bantu males having a diet relatively good if somewhat high in carbohydrate Youmans et al (1943) using the micro Kjeldahl and biuret methods found in an ill fed population in middle Tennessee that both whites and Africans had a mean serum-protein value under 7 3 g per 100 ml, which was often associated with reduced albumin and raised globulin values

Snell (1950) examined 935 Japanese, who were so called "healthy" people though a large proportion of them suffered from hookworm, ascaris, and other worm infestations, and the incidence of tuberculosis also was probably high The diet was largely rice with fish as the source of animal protein The serum protein values determined by the copper sulphate method were significantly raised above the European standard in all age groups and in both sexes, and reached a mean level of 7 7 g per 100 ml in adult women

The pathological or physiological condition underlying the high values for serum protein in the different racial groups in Fiji and Samoa is at present unknown It should be noted, however, that the individual often appeared to be in fine physical condition, witness the athletic prowess of the Fijians, and yet the sera of these magnificent specimens showed the same high protein values Injury or infection and liver disease may cause an increase in the globulin fraction of the serum protein (Marrack and Hoch 1949) which in certain conditions such as kala azar may result in total values as high as 12 0 g per 100 ml serum It is thought that, in kala-azar as in malaria and some other infections, liver injury plays a part as well as the immune reaction In these conditions it is the γ globulin fraction that is so markedly increased It is known also that serum globulins increase in conditions associated with lipæmia and high serum values for cholesterol

In the different series quoted above, the common factors seem to have been relative poverty, a high incidence of infection and infestation with intestinal parasites, and a high carbohydrate diet, often, but not always deficient in animal protein and fat It should be noted, however, that such deficient diets may be associated in the same peoples with hypoproteinæmia (Youmans et al 1943, Trowell and Muwazi 1945, Altmann 1948, Walt and Wills 1950) In our present series, infestation with intestinal worms, including hookworm and ascaris, was common, though clinical signs and anæmia were rarely seen Children up to the age of 7 or 9 years also suffered severely from sores, particularly of the arms and legs, which were variously ascribed to impetigo, infected scabies, and scratched mosquito bites As the rise in serum protein values did not occur in the Fijian and Indian children until a later age than in the Samoans, intestinal parasites and the common infections of the skin can be excluded as major factors in the production increase of the increased serum protein Similarly such tropical diseases as malaria, kala azar, and filarial infections can be excluded, since the first two do not occur in Fiji and the third is extremely uncommon at the present day The prevalence of yaws, however, is a major problem in Samoa, where the disease is often acquired in the first two years of life and is very severe In Fiji, though we saw only a few cases, mostly in school children, the majority of the population is said to have had yaws, but to have had sufficient treatment to suppress the symptoms and make the individual no longer infectious though not enough to reverse the almost universally positive Kahn reaction The high sedimentation rate reported for many seemingly healthy Fijians and Samoans is apparently related to the presence of a positive Kahn reaction If infection with yaws is related to a high serum protein level and if infection generally occurs earlier in the Samoans than in the Fijians, the disparity in the age at which the serum protein level rises in the two races would be explained The Indians in Fiji are said not to suffer from yaws and there was no obvious clue to the possible cause of the somewhat high values in the older age groups The possible significance of diet is difficult to assess since it varied widely in amount and between the different racial groups studied Further work should be directed to a study of the diet in the different racial groups and to an investigation of the relation between the high serum protein values and the occurrence of a positive Kahn reaction and of yaws in all its stages A study should also be made of the other infections such as those due to the salmonella group of organisms which also cause a rise in the serum γ globulin due to antibody formation

SUMMARY

The serum protein was estimated by the copper sulphate method in 823 Fijians and Indians in Fiji and 249 Samoans in Samoa

The people examined were as far as possible a cross section of the three races, of all age groups, and, with few exceptions, apparently healthy

There was no significant difference between the values obtained for the two sexes and these were grouped together

The mean serum protein levels of all three races and all age groups after 6–14 years were significantly higher than the levels usual in Europeans, including Europeans living in Fiji and Samoa

The rise appeared by the age of 2–5 years in Samoan children

The values for Samoans were significantly higher than for the other two races in all age groups over 2 years.

Electrophoretic analysis of serum from a healthy young Fijian male showed a γ globulin value about twice the normal figure

The significance of these findings and their possible relationship to infection with yaws is discussed

We wish to thank the many assistant medical practitioners, schoolmasters and schoolmistresses, health sisters, and nurses of many races who, by their willing coöperation made this work possible We are deeply indebted to Mr Pery Johnston, superintendent of the laboratory of the Colonial Memorial Hospital, Suva, for technical help given most ungrudgingly, and to Dr J M Cruikshank, inspector general, South Pacific Health Service, Suva, Fiji, and to Dr J C. Lopdell, director of public health, Apia, Samoa Our thanks are due to the British Colonial Development Fund, the N.Z Department of Health, and the N.Z Department of Island Territories for providing the funds that enabled us to carry out the investigation

RECOVERY OF HUMAN RED BLOOD-CELLS AFTER FREEZING

H. A. SLOVITER*
M.D., Ph.D. Pennsylvania
From the National Institute for Medical Research, Mill Hill, London

It was recently discovered by Smith (1950) that the hæmolysis which normally occurs after freezing and thawing of whole blood can be prevented by the prior addition of a diluent containing glycerol. She found that if the final concentration of glycerol in the diluted blood was between 10% and 20% rapid freezing in a bath at −79°C, followed by rapid thawing at 40°C, left nearly all the red blood-cells intact. Red blood cells of both the human and the rabbit were used in these experiments. Other reports (Florio et al. 1943, Luyet 1949, Strumia 1949, Griffits et al. 1949, Walter and Gibson 1949) of the survival of red blood cells after freezing and thawing describe methods which involve either very small quantities of blood or very special conditions.

Red blood cells which contain glycerol (whether previously frozen or not) hæmolyse rapidly when placed in plasma or other isotonic media not containing glycerol. This occurs because the glycerol has increased the osmotic tension of the contents of the cell. The hypertonic cell draws in water rapidly, swells, and ruptures. It was evident, therefore, that to make further use of the cells which have been frozen and thawed in the presence of glycerol it would be necessary to recover the cells by some method other than rapid washing. The slow removal of glycerol from red blood cells has been successfully accomplished by dialysis against saline solutions containing progressively decreasing concentrations of glycerol. Red blood-cells which have thus been freed of glycerol can then be separated by centrifuging, washed and suspended in plasma.

PROCEDURE

The complete procedure for small quantities of blood is as follows:

1. Equal volumes of whole blood and glycerol diluent (30 g. glycerol and 0·85 g. NaCl per 100 ml. of solution) are well mixed in an ordinary test-tube and allowed to stand at 5°C for one to two hours.

2. The test-tube is immersed in a −79°C bath (solid CO_2, alcohol).

3. After remaining in the −79°C bath for several hours the mixture is thawed rapidly by immersing the test-tube in a 37°C water bath only until the contents have liquefied.

4. The thawed mixture is dialysed at 5°C successively against 6%, 4%, 2%, and 0% glycerol in 0·85% NaCl solution for three hours or more at each concentration. Dialysis is conveniently performed in a bag made by tying off the ends of a section of cellulose sausage casing.

TABLE I—EXPERIMENTAL CONDITIONS

Treatment	Packed cell volume (%)	Cell-count (million per c.mm.)	Hæmolysis
Equilibrated not frozen	20·0	1·77	None
Equilibrated frozen rapidly thawed rapidly	20·0 21·0 21·0	1·64 1·78 1·77	Very slight
Equilibrated frozen rapidly, thawed slowly	19·5	1·63	Slight
Equilibrated, frozen slowly thawed slowly	15·0	1·23	Moderate
Not equilibrated frozen rapidly thawed slowly	14·5	1·12	Heavy

5. The cells are separated by centrifuging and washed three times with cold 0·85% NaCl solution. The cells are then suspended in plasma.

EXPERIMENTAL CONDITIONS

The experimental factors which are of some importance in this procedure are: (1) the concentration of glycerol, (2) the equilibration of the cells with glycerol prior to freezing, (3) the rate of freezing, and (4) the rate of thawing. Data from experiments evaluating the last three of these factors are shown in table I.

The exact concentration of glycerol is not critical. A final concentration of glycerol between 10% and 20% will prevent hæmolysis. Accordingly, the diluent used contained 30% glycerol, this on mixing with an equal volume of blood yields a final glycerol concentration of 15%.

If the blood and the glycerol solution are mixed immediately before freezing, considerable hæmolysis results. In the procedure adopted the blood was equilibrated with the glycerol at 5°C for an hour or longer prior to freezing.

TABLE II—RECOVERY OF HUMAN RED BLOOD-CELLS

Sample	Packed cell volume (%)	Cell-count (million per c.mm.)	Cells recovered (%)
Original blood A	41	3·4	—
A 1	35	2·8	82
A 2	36	3·2	94
A 3	35	3·2	94
A 4	34	3·1	91
Original blood B	44	3·8	—
B 1	35	3·0	79
B 2	38	3·4	90
B 3	36	3·2	84
B 4	35	3·1	82

When an ordinary 6 × ½ in. test-tube containing 10 ml. of blood-glycerol solution mixture is immersed in a −79°C bath, the central portion of the mixture reaches −70°C in approximately two minutes. If the mixture is gradually brought to −70°C over the course of about thirty minutes, appreciable hæmolysis results.

The rate of thawing of the frozen cells is of less importance than the rate of freezing. If the frozen mixture is allowed to thaw in air at room-temperature a little hæmolysis results. Minimal hæmolysis results when the mixture is thawed rapidly.

RESULTS

Quantitative experiments have been performed to measure the recoveries of human red blood cells carried through the complete procedure. The freezing was carried out in ordinary 6 × ½ in. test tubes. Starting with accurately measured 5 ml. portions of blood the recovered cells were suspended in plasma to a total volume of 5 ml. Recoveries were calculated from cell counts of the original blood and of the suspension of recovered cells. Experiments were done with portions drawn from two different bottles of human blood. The results obtained are shown in table II.

The recovered red blood cells are normal in appearance and have the same resistance to hypotonic solutions as the original cells. The plasma suspensions of recovered cells and the original blood show approximately the same rate of deterioration in storage at 5°C.

Problems arising from the present work which are now being investigated include the effect of long time storage at −79°C on the survival of the red blood-cells, the in vivo survival of the recovered red blood cells, the freezing of larger quantities of blood, and the mechanism whereby glycerol prevents hæmolysis.

SUMMARY

Human blood has been rapidly frozen and rapidly thawed in the presence of glycerol, as previously described by Smith (1950).

* Damon Runyon senior clinical research fellow 1950–51.

sodium ions in solution can be exchanged for those on the resin A series of experiments have been done to test quantitatively the exchange properties of such modified resins In the first place the resin was partially presaturated by treating it with amounts of potassium and calcium below its exchange capacity (1 m eq of each to 1 g of resin), whereas in later experiments it was completely saturated (6 m eq to 1 g of resin), the subsequent behaviour of the modified resins towards sodium chloride solution being observed in each case

The first experiments showed that the treatment with sodium of a partially saturated resin merely replaces the hydrogen remaining in the resin by sodium, and causes no appreciable replacement of the cation bound during the preliminary treatment It seems, therefore, that nothing is to be gained by such partial presaturation

In the second group of experiments the resin was (1) saturated with calcium and then studied as an exchange material (*a*) for sodium, and (*b*) for potassium, calcium, and sodium ions in solution in the relative proportions present in an average meal (with added sodium chloride), (2) the resin was saturated with potassium before being treated with (*a*) sodium and (*b*) potassium, calcium, and sodium as before The results were as follows

(1*a*) In first stage, 1 g of resin exchanged 2 55 m eq Ca (100% saturation)

In second stage when 1 g of calcium saturated resin was treated with 6 0 m eq of sodium chloride, the Na uptake was 1 30 m eq and the Ca release 1 30 m eq—i e, 51% replacement

(2*a*) In first stage, 1 g of resin exchanged 2 30 m eq of potassium (92% saturation)

In second stage, when 1 g of potassium saturated resin was treated with 6 0 m eq of sodium chloride, the Na uptake was 1 35 m eq and the K release 1 30 m eq—i e, 57% replacement, with a small additional hydrogen exchange as a result of incomplete presaturation

(1*b*) First stage as in 1*a*

In second stage, when 1 g of calcium saturated resin was treated with solution containing 6 0 m eq of Na, 1 5 m eq of K, and 0 5 m eq of Ca, the final solution showed a Na uptake of 0 6 m eq, a K uptake of 0 4 m eq, and a Ca release of 1 0 m eq—i e, 39% replacement

(2*b*) First stage as in 2*a*

In second stage, when 1 g of potassium saturated resin was treated with solution containing 6 0 m eq of Na, 1 5 m eq of K, and 0 5 m eq of Ca, the final solution showed a Na uptake of 1 0 m eq, a K release of 1 2 m eq, and a Ca uptake of 0 4 m eq—i e, 52% replacement, with an additional hydrogen exchange for calcium sufficient for full saturation of the resin

It is evident from these few in vitro experiments that neither calcium nor potassium resins would be quantitatively efficient substitutes for the original hydrogen exchange resin The effects of the relative affinities for the resin of the three elements studied are clearly demonstrated It is unfortunate, from the clinical point of view, that the resin's affinity for sodium is so much weaker than for the other metals It follows that acidosis and deficiencies of potassium and calcium could not be efficiently prevented by preliminary saturation of the resin with these metals

Effect of Magnesium Trisilicate on Cation Exchange

The idea occurred to me that the problem of acidosis might be solved by adding magnesium trisilicate to the exchange system Parallel experiments with and without added magnesium trisilicate were therefore performed and the efficiency of the trisilicate as an acid adsorbent was determined by alkalimetric titration of the exchange solution The results were as follow

Experiment 1—1g of resin alone, and with 0 2 g of magnesium trisilicate, was equilibrated with a solution containing 6 0 m eq of sodium chloride With the resin alone, the Na uptake was 2 25 m eq and the H release 2 24 m eq With the resin + 0 2 g of trisilicate, the Na uptake was 1 54 m.eq and the H release 1 35 m eq

Experiment 2—1 g of resin alone, and with 0 5 g of magnesium trisilicate, was equilibrated with a solution containing 3 0 m eq of potassium chloride With the resin alone the K uptake was 1 88 m eq and the H release 1 88 m eq With the resin + 0 5 g of trisilicate, the K uptake was 1 14 m eq and the H release nil

These experiments show that the trisilicate leads to a serious loss of efficiency of cation exchange The reason has not been investigated It may be that a small amount of magnesium is liberated from the trisilicate and competes with sodium or potassium for the resin, or perhaps that, owing to its small particle size and bulkiness, the trisilicate hinders cation exchange mechanically under the conditions of the experiments

CATION EXCHANGE UNDER GASTRO INTESTINAL CONDITIONS

The behaviour of the resin has been studied under experimental conditions similar as regards mineral composition to those of the stomach and small intestine.

The mineral content of a simple everyday diet was determined from the analytical data of McCance and Widdowson (1946) and the daily food bulk was assumed to be 2 5 litres The food meets with a gastric secretion assumed to amount to 500 ml per day and containing an average of 135 m eq of H ion and 40 m eq of Na ion per litre at the peak of digestion The next stage is contact with intestinal secretions of about 3 litres per day, though there are considerable variations in the electrolyte patterns of the several intestinal secretions, the base is essentially sodium at a concentration of 175 m eq per litre These two stages have been imitated in the two phases of the in vitro experiments

Setting out the data in a numerical form, we have

Diet contains Na 160 m eq, K 50 m eq, Ca 20 m eq Total cation=230 m eq per day (allowing for additional salt in cooking, &c) Theoretical resin requirement=90 g Food bulk=2500 ml per day

Gastric secretion 500 ml per day at peak of digestion, composed of 135 m eq of H ion and 40 m eq of Na ion per litre

Intestinal secretions 3000 ml per day, containing 175 m eq of Na ion per litre

For experimental purposes it was found convenient to take a hundredth part of each of these amounts

Phase 1 (Gastric)

Representing food 25 ml of solution containing 1 60 m eq of Na, 0 50 m eq of K, and 0 20 m eq of Ca

Representing gastric secretion 5 ml of solution containing 0 70 m eq of H ion as HCl and 0 20 m eq of Na.

The two solutions, with 0 9 g of resin added, were put in the mechanical mixer for 3 hours

At the end of phase 1 the total cation exchange, calculated from a duplicate experiment, was 1 48 m eq (uptake of Na 0 93, K 0 35, and Ca 0 20 m eq)

Phase 2 (Intestinal)

Representing intestinal secretions 30 ml of 0 9% (*w*/*v*) NaCl, equivalent to 4 61 m eq of Na

This was added to the tube containing the end products of phase 1, and mixed for an hour

At the end of phase 2 the total cation exchange was 1 56 m eq (uptake of Na 1 13, K 0 23, and Ca 0 20 m eq)

These results show that at the end of the final stage the resin has exchanged 1 74 m eq of cation per gramme (i e, 70% of its theoretical saturation) The over all efficiency of the process, calculated on the original amount of cation in the "food," was 76%, in these experimental conditions, the resin removed 70% of the sodium, 46% of the potassium, and all the calcium As might have been expected there was an additional exchange on the resin for sodium, accompanied by a release of potassium An experiment of this kind of course cannot determine the effects of intestinal absorption of cation, but the absorption of potassium by the gut should improve the over all uptake of sodium

DISCUSSION

The clinical applications of cation exchange resins have presented some interesting problems to both physician and biochemist These resins are highly efficient under certain conditions—e g , where weak solutions of inorganic salts slowly percolate through beds of the resin The present experiments show that zeo karb 225 cannot efficiently remove cations from solutions if it is presented with a relatively large mass of the salt, except perhaps in the case of salts of metals with exceptionally high exchange potentials The apparently unfavourable exchange properties of the resin studied here, from the clinical point of view, arising from its unduly high affinity for calcium and potassium compared with sodium, are likely to be counterbalanced to some extent by the preponderance of sodium in the alimentary tract

Judging by these in vitro experiments, preliminary saturation of the resin with calcium and potassium will not prevent the possible production of calcium and potassium deficiencies, or of acidosis, when the resin is being used to abstract sodium from the diet after ingestion, because of the quantitatively poor power of sodium to replace these other metallic ions The deficiencies may, on the other hand, be corrected by giving supplementary doses of the metals concerned at suitable times of the day, when they will be absorbed by the gut before they can be acted on by the resin The experiment simulating gastro intestinal conditions suggests that satisfactory results may be attained by giving the resin in somewhat larger doses than are theoretically necessary, or by restricting the patient's sodium intake

The treatment of patients with cation exchange resins will have to be carefully controlled. In particular, the state of the renal function should be determined at the outset, and periodical determinations of the plasma-alkali reserve, serum calcium and serum potassium, and of the urinary sodium will provide the data needed for assessing the efficiency of the resin

SUMMARY

The cation exchange resin, ‘ Zeo Karb 225,’ has been examined quantitatively with regard to its exchange efficiency towards sodium, potassium, and calcium ions under various conditions

The resin shows a very high relative affinity for calcium, a lower one for potassium, and a much lower one for sodium

Presaturation of the resin with calcium and potassium gave products whose exchange efficiency for sodium was poor

Magnesium trisilicate is capable of eliminating acid produced during cation exchange, but it was found to cause a well marked loss of efficiency of the resin

An in vitro experiment simulating the mineral conditions in the alimentary tract was devised in order to study the effect on cation exchange of the great preponderance of sodium ions

I wish to acknowledge the critical interest and pertinent suggestions of my colleague Dr J S McKinnell during these investigations.

FORMERLY
HOUSE SURGEON

PROVIDENCE FREE HOSPITAL, ST HELENS, LANCS

CONGENITAL indifference to pain has been described by Schilder and Stengel (1931), who saw ten cases and related the symptoms to a lesion of the left supramarginal gyrus Hemphill and Stengel (1940) reported a further case, which followed cerebral trauma and exhibited an indifference to painful stimuli as well as to abnormally strong visual and auditory stimuli and pure word-deafness There was a fracture of the squamous part of the left temporal bone as well as of the left petrous bone Ford and Wilkins (1938) described three cases, two of which showed mild mental retardation, the third patient being apparently of normal intelligence Critchley (1934) recorded one case of his own and cited three others Rubins and Friedman (1948) had four cases all with lesions in or around the supramarginal gyrus and showing various degrees of aphasia Arbuse et al (1949) reported a case with many similarities to the one we are about to describe, and summarised the literature Recently Leys (1950) has also reported a case

A girl, aged 7 years, was brought to hospital because she walked badly, did not talk clearly or play with other children, and had had a cough for five years She was the third of four children, the rest of the family being healthy Her birth had been at full term after a normal pregnancy, and there was no history of birth injury Developmental progress had been slow, and she had only just begun to sit up at the age of 1 year when she had ‘ meningitis,’ but an accurate report of this illness could not be obtained She had first spoken at the age of 2, and walked at the age of $2^1/_2$ She had had measles, two attacks of pneumonia and a facial laceration, extending from the angle of the mouth almost to the ear, which had been sutured apparently without causing any pain The mother complained that corporal punishment was useless because the child was apparently insensitive to pain.

Examination revealed abnormalities in both the nervous and the respiratory systems Save for a few words the patient would not talk to adults, though she would talk to children of about half her own age , her speech was then heard to be indistinct She had a coarse tremor of the head and hands, and her gait was slightly unsteady Her pupils were small and oval, and responded very sluggishly to light after she had been in the dark for half an hour , but they responded well to accommodation The other cranial nerves appeared to be normal, as were the superficial and deep reflexes Sensation of light touch, position, and hot and cold was accurate but there seemed to be no reaction whatever to pain. A pin thrust deeply into the child's back while her attention was diverted produced no reaction even when her attention was drawn to what was going to be done she evinced no sign of fear or apprehension. Pinching the tendo achillis with the utmost force was received with the same equanimity as were both venepuncture and lumbar puncture

Signs of a left basal bronchiectasis were confirmed by bronchography No other abnormality was found The blood Wassermann reaction was negative both before and after a provocative dose of arsenic The cerebrospinal fluid was normal to all routine tests, including the Wassermann and gold curve A blood count was normal as was radiography of the skull The child's intelligence quotient was estimated to be 72

It may be suggested that in the above case the condition is not congenital but due to the illness at the age of 1 year Though this cannot be denied, the history of retarded development before this illness suggests a previous abnormality of the brain An association between indifference to pain and slight mental retardation is evident in many cases previously described, but in the present case that the abnormal reaction to pain is not part of the general mental retardation seems clear sodium ions in solution can be exchanged for those on the resin. A series of experiments have been done to test quantitatively the exchange properties of such modified resins. In the first place the resin was partially presaturated by treating it with amounts of potassium and calcium below its exchange capacity (1 m.eq. of each to 1 g. of resin), whereas in later experiments it was completely saturated (6 m.eq. to 1 g. of resin), the subsequent behaviour of the modified resins towards sodium chloride solution being observed in each case.

The first experiments showed that the treatment with sodium of a partially saturated resin merely replaces the hydrogen remaining in the resin by sodium, and causes no appreciable replacement of the cation bound during the preliminary treatment. It seems, therefore, that nothing is to be gained by such partial presaturation.

In the second group of experiments the resin was (1) saturated with calcium and then studied as an exchange material (*a*) for sodium, and (*b*) for potassium, calcium, and sodium ions in solution in the relative proportions present in an average meal (with added sodium chloride); (2) the resin was saturated with potassium before being treated with (*a*) sodium and (*b*) potassium, calcium, and sodium as before. The results were as follows:

(1*a*) In first stage, 1 g. of resin exchanged 2.55 m.eq. Ca (100% saturation).

In second stage when 1 g. of calcium saturated resin was treated with 6.0 m.eq. of sodium chloride, the Na uptake was 1.30 m.eq. and the Ca release 1.30 m.eq.—i.e., 51% replacement.

(2*a*) In first stage, 1 g. of resin exchanged 2.30 m.eq. of potassium (92% saturation).

In second stage, when 1 g. of potassium saturated resin was treated with 6.0 m.eq. of sodium chloride, the Na uptake was 1.35 m.eq. and the K release 1.30 m.eq.—i.e., 57% replacement, with a small additional hydrogen exchange as a result of incomplete presaturation.

(1*b*) First stage as in 1*a*.

In second stage, when 1 g. of calcium saturated resin was treated with solution containing 6.0 m.eq. of Na, 1.5 m.eq. of K, and 0.5 m.eq. of Ca, the final solution showed a Na uptake of 0.6 m.eq., a K uptake of 0.4 m.eq., and a Ca release of 1.0 m.eq.—i.e., 39% replacement.

(2*b*) First stage as in 2*a*.

In second stage, when 1 g. of potassium saturated resin was treated with solution containing 6.0 m.eq. of Na, 1.5 m.eq. of K, and 0.5 m.eq. of Ca, the final solution showed a Na uptake of 1.0 m.eq., a K release of 1.2 m.eq., and a Ca uptake of 0.4 m.eq.—i.e., 52% replacement, with an additional hydrogen exchange for calcium sufficient for full saturation of the resin.

It is evident from these few in vitro experiments that neither calcium nor potassium resins would be quantitatively efficient substitutes for the original hydrogen exchange resin. The effects of the relative affinities for the resin of the three elements studied are clearly demonstrated. It is unfortunate, from the clinical point of view, that the resin's affinity for sodium is so much weaker than for the other metals. It follows that acidosis and deficiencies of potassium and calcium could not be efficiently prevented by preliminary saturation of the resin with these metals.

Effect of Magnesium Trisilicate on Cation Exchange

The idea occurred to me that the problem of acidosis might be solved by adding magnesium trisilicate to the exchange system. Parallel experiments with and without added magnesium trisilicate were therefore performed and the efficiency of the trisilicate as an acid adsorbent was determined by alkalimetric titration of the exchange solution. The results were as follow:

Experiment 1.—1g. of resin alone, and with 0.2 g. of magnesium trisilicate, was equilibrated with a solution containing 6.0 m.eq. of sodium chloride. With the resin alone, the Na uptake was 2.25 m.eq. and the H release 2.24 m.eq. With the resin + 0.2 g. of trisilicate, the Na uptake was 1.54 m.eq. and the H release 1.35 m.eq.

Experiment 2.—1 g. of resin alone, and with 0·5 g. of magnesium trisilicate, was equilibrated with a solution containing 3.0 m.eq. of potassium chloride. With the resin alone the K uptake was 1.88 m.eq. and the H release 1.88 m.eq. With the resin + 0.5 g. of trisilicate, the K uptake was 1.14 m.eq. and the H release nil.

These experiments show that the trisilicate leads to a serious loss of efficiency of cation exchange. The reason has not been investigated. It may be that a small amount of magnesium is liberated from the trisilicate and competes with sodium or potassium for the resin; or perhaps that, owing to its small particle size and bulkiness, the trisilicate hinders cation exchange mechanically under the conditions of the experiments.

CATION EXCHANGE UNDER GASTRO-INTESTINAL CONDITIONS

The behaviour of the resin has been studied under experimental conditions similar as regards mineral composition to those of the stomach and small intestine.

The mineral content of a simple everyday diet was determined from the analytical data of McCance and Widdowson (1946) and the daily food bulk was assumed to be 2.5 litres. The food meets with a gastric secretion assumed to amount to 500 ml. per day and containing an average of 135 m.eq. of H ion and 40 m.eq. of Na ion per litre at the peak of digestion. The next stage is contact with intestinal secretions of about 3 litres per day; though there are considerable variations in the electrolyte patterns of the several intestinal secretions, the base is essentially sodium at a concentration of 175 m. eq. per litre. These two stages have been imitated in the two phases of the in vitro experiments.

Setting out the data in a numerical form, we have:

Diet: contains Na 160 m.eq., K 50 m.eq., Ca 20 m.eq. Total cation=230 m.eq. per day (allowing for additional salt in cooking, &c.). Theoretical resin requirement=90 g. Food bulk=2500 ml. per day.

Gastric secretion: 500 ml. per day at peak of digestion, composed of 135 m.eq. of H ion and 40 m.eq. of Na ion per litre.

Intestinal secretions: 3000 ml. per day, containing 175 m.eq. of Na ion per litre.

For experimental purposes it was found convenient to take a hundredth part of each of these amounts.

Phase 1 (Gastric)

Representing food: 25 ml. of solution containing 1.60 m.eq. of Na, 0.50 m.eq. of K, and 0.20 m.eq. of Ca.

Representing gastric secretion: 5 ml. of solution containing 0.70 m.eq. of H ion as HCl and 0.20 m.eq. of Na.

The two solutions, with 0.9 g. of resin added, were put in the mechanical mixer for 3 hours.

At the end of phase 1 the total cation exchange, calculated from a duplicate experiment, was 1.48 m.eq. (uptake of Na 0.93, K 0.35, and Ca 0.20 m.eq.).

Phase 2 (Intestinal)

Representing intestinal secretions: 30 ml. of 0.9% (*w*/*v*) NaCl, equivalent to 4.61 m.eq. of Na.

This was added to the tube containing the end products of phase 1, and mixed for an hour.

At the end of phase 2 the total cation exchange was 1.56 m.eq. (uptake of Na 1.13, K 0.23, and Ca 0.20 m.eq.).

These results show that at the end of the final stage the resin has exchanged 1.74 m.eq. of cation per gramme (i.e., 70% of its theoretical saturation). The over-all efficiency of the process, calculated on the original amount of cation in the "food," was 76%; in these experimental conditions, the resin removed 70% of the sodium, 46% of the potassium, and all the calcium. As might have been expected there was an additional exchange on the resin for sodium, accompanied by a release of potassium An experiment of this kind of course cannot determine the effects of intestinal absorption of cation, but the absorption of potassium by the gut should improve the over all uptake of sodium

DISCUSSION

The clinical applications of cation exchange resins have presented some interesting problems to both physician and biochemist These resins are highly efficient under certain conditions—e g , where weak solutions of inorganic salts slowly percolate through beds of the resin The present experiments show that zeo karb 225 cannot efficiently remove cations from solutions if it is presented with a relatively large mass of the salt, except perhaps in the case of salts of metals with exceptionally high exchange potentials The apparently unfavourable exchange properties of the resin studied here, from the clinical point of view, arising from its unduly high affinity for calcium and potassium compared with sodium, are likely to be counterbalanced to some extent by the preponderance of sodium in the alimentary tract

Judging by these in vitro experiments, preliminary saturation of the resin with calcium and potassium will not prevent the possible production of calcium and potassium deficiencies, or of acidosis, when the resin is being used to abstract sodium from the diet after ingestion, because of the quantitatively poor power of sodium to replace these other metallic ions The deficiencies may, on the other hand, be corrected by giving supplementary doses of the metals concerned at suitable times of the day, when they will be absorbed by the gut before they can be acted on by the resin The experiment simulating gastro intestinal conditions suggests that satisfactory results may be attained by giving the resin in somewhat larger doses than are theoretically necessary, or by restricting the patient's sodium intake

The treatment of patients with cation exchange resins will have to be carefully controlled In particular, the state of the renal function should be determined at the outset, and periodical determinations of the plasma alkali reserve, serum calcium and serum potassium, and of the urinary sodium will provide the data needed for assessing the efficiency of the resin

SUMMARY

The cation exchange resin, 'Zeo Karb 225,' has been examined quantitatively with regard to its exchange efficiency towards sodium, potassium, and calcium ions under various conditions

The resin shows a very high relative affinity for calcium, a lower one for potassium, and a much lower one for sodium

Presaturation of the resin with calcium and potassium gave products whose exchange efficiency for sodium was poor

Magnesium trisilicate is capable of eliminating acid produced during cation exchange, but it was found to cause a well marked loss of efficiency of the resin

An in vitro experiment simulating the mineral conditions in the alimentary tract was devised in order to study the effect on cation exchange of the great preponderance of sodium ions

I wish to acknowledge the critical interest and pertinent suggestions of my colleague Dr J S McKinnell during these investigations.

CONGENITAL INDIFFERENCE TO PAIN

H G FARQUHAR
B.M. Oxfd, M.R C P , D C H
VISITING PÆDIATRICIAN

T SUTTON
M B N U I
FORMERLY HOUSE SURGEON

PROVIDENCE FREE HOSPITAL, ST HELENS, LANCS

CONGENITAL indifference to pain has been described by Schilder and Stengel (1931), who saw ten cases and related the symptoms to a lesion of the left supramarginal gyrus Hemphill and Stengel (1940) reported a further case, which followed cerebral trauma and exhibited an indifference to painful stimuli as well as to abnormally strong visual and auditory stimuli and pure word-deafness There was a fracture of the squamous part of the left temporal bone as well as of the left petrous bone Ford and Wilkins (1938) described three cases, two of which showed mild mental retardation, the third patient being apparently of normal intelligence Critchley (1934) recorded one case of his own and cited three others Rubins and Friedman (1948) had four cases all with lesions in or around the supramarginal gyrus and showing various degrees of aphasia Arbuse et al (1949) reported a case with many similarities to the one we are about to describe, and summarised the literature Recently Leys (1950) has also reported a case

A girl, aged 7 years, was brought to hospital because she walked badly, did not talk clearly or play with other children, and had had a cough for five years She was the third of four children, the rest of the family being healthy Her birth had been at full term after a normal pregnancy, and there was no history of birth injury Developmental progress had been slow, and she had only just begun to sit up at the age of 1 year when she had "meningitis," but an accurate report of this illness could not be obtained. She had first spoken at the age of 2, and walked at the age of $2^1/_2$ She had had measles two attacks of pneumonia, and a facial laceration, extending from the angle of the mouth almost to the ear, which had been sutured apparently without causing any pain The mother complained that corporal punishment was useless because the child was apparently insensitive to pain.

Examination revealed abnormalities in both the nervous and the respiratory systems Save for a few words the patient would not talk to adults, though she would talk to children of about half her own age , her speech was then heard to be indistinct She had a coarse tremor of the head and hands, and her gait was slightly unsteady Her pupils were small and oval, and responded very sluggishly to light after she had been in the dark for half an hour , but they responded well to accommodation The other cranial nerves appeared to be normal, as were the superficial and deep reflexes Sensation of light touch position, and hot and cold was accurate but there seemed to be no reaction whatever to pain A pin thrust deeply into the child's back while her attention was diverted produced no reaction , even when her attention was drawn to what was going to be done she evinced no sign of fear or apprehension Pinching the tendo achillis with the utmost force was received with the same equanimity as were both venepuncture and lumbar puncture

Signs of a left basal bronchiectasis were confirmed by bronchography No other abnormality was found The blood Wassermann reaction was negative both before and after a provocative dose of arsenic The cerebrospinal fluid was normal to all routine tests including the Wassermann and gold curve A blood count was normal, as was radiography of the skull The child s intelligence quotient was estimated to be 72

It may be suggested that in the above case the condition is not congenital but due to the illness at the age of 1 year Though this cannot be denied, the history of retarded development before this illness suggests a previous abnormality of the brain An association between indifference to pain and slight mental retardation is evident in many cases previously described, but in the present case that the abnormal reaction to pain is not part of the general mental retardation seems clear from the child's accurate recognition of other sensory stimuli

CALCIUM METABOLISM IN HYPERTHYROIDISM

THE EFFECT OF THIOURACIL

J GREEN
M.B Glasg, M R C P E

A LYALL
M A, M D Aberd, F R C.P

LECTURERS ON CLINICAL CHEMISTRY IN THE UNIVERSITY OF ABERDEEN

THE occurrence of osteoporosis in hyperthyroidism was known to von Recklinghausen and Askanazy (Hunter 1930) The metabolic studies of Aub et al (1929) and Hunter (1935) showed that calcium is lost in both fæces and urine, the excessive fæcal excretion of calcium was attributed to "intestinal hurry," but the cause of the increased urinary calcium excretion remained obscure The studies of Robertson (1942) pointed to an effect of thyroid hormone on renal epithelium

The effect of thiouracil offers a new approach to this problem (Lundbaek 1947) We have accordingly tried to find whether the disturbance of calcium and phosphorus metabolism in hyperthyroidism is restored to normal by thiouracil treatment, and whether changes in their day to day excretion can be correlated with nitrogen excretion or any other factor

METHOD

Six cases of severe hyperthyroidism were selected five because of their high urinary calcium excretion, and the remaining one for comparison They were kept on ordinary ward diet containing 0 5–0 6 g of calcium per day It was presumed that any variation in urinary calcium excretion due to dietary variation about this level would not affect the significance of the changes observed No complete balance studies were made in this group because of the difficulty of providing duplicate diets

Daily collections of 24 hour samples of urine were made Standard methods were used in the estimation of urinary calcium (Godden 1937), urinary phosphorus (Fiske and Subbarow 1925), urinary nitrogen (Koch and McMeekin 1924), serum calcium (Clark and Collip 1925), and serum phosphorus (Fiske and Subbarow 1925)

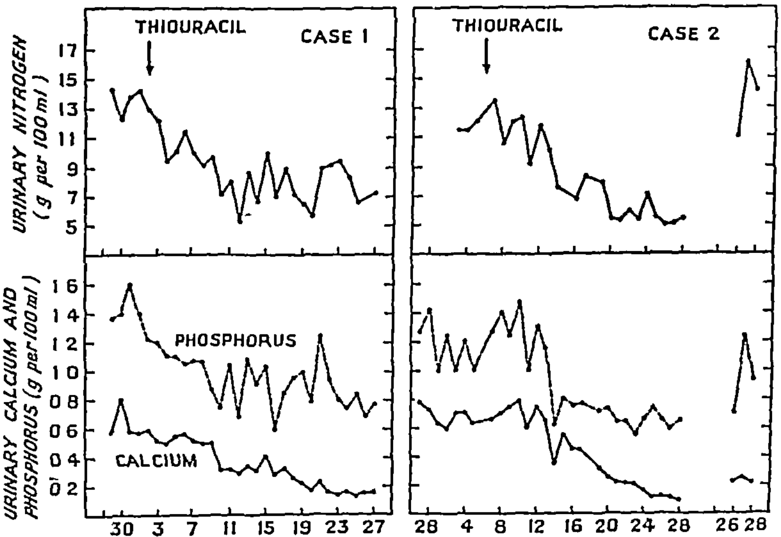

Fig 1—Urinary calcium phosphorus and nitrogen in cases 1 and 2.

CASE RECORDS

Case 1—A housewife, aged 31, was admitted on Jan. 17, 1949, with 7 months' history of tiredness, excitability, &c She was a typical case of hyperthyroidism, her basal metabolic rate (B M R) being + 22% serum calcium 10·5 mg per 100 ml., serum phosphorus 5 0 mg, and alkaline phosphatase 10 units on Feb 2 Treatment with thiouracil 0 2 g b d was started on Feb 2 She responded well and was put on iodine on March 4, as a prelude to successful thyroidectomy on March 16

Case 2—A factor, aged 47, was admitted on Feb 24, 1949, with 3 months' history of breathlessness, nervousness, and loss of weight He showed obvious signs of hyperthyroidism, and his B M R on Feb 26, was + 44% His serum calcium was 10 8 mg per 100 ml, serum phosphorus 4 6 mg, and alkaline phosphatase 8 units Treatment with thiouracil 0 2 g t.d. was started on March 6 Considerable improvement followed, but thyroidectomy was postponed to allow removal of a nasal polypus The patient was discharged for six months on thiouracil, iodisation and thyroidectomy followed in September, 1949

Case 3—A farmer, aged 46, had had intermittent dyspepsia for 16 years A barium meal before admission showed a small gastric ulcer (May 9, 1949) Some tremor of hands, exophthalmos, and enlargement of the thyroid were noted, and the B M R on May 15 was + 40% Ten days later the patient developed pyloric stenosis, which precipitated a thyroid crisis, and large doses of iodine were given Thiouracil treatment was started on May 20 Clinical improvement was noted, but the B M R a month later was still +16% The serum calcium at this time was 10 mg per 100 ml, serum phosphorus 3 9 mg, and alkaline phosphatase 6 5 units The patient continued to improve, and on July 13, after preoperative iodine, a successful thyroidectomy was performed

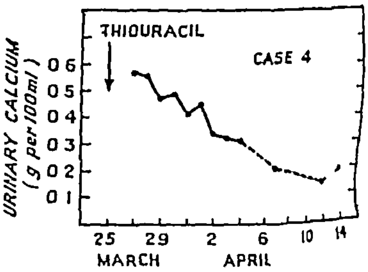

Fig 3—Urinary calcium in case 4.

Case 4—A fisherman aged 54, was admitted on March 21, 1949, with 6 years' history of intermittent excitability, breathlessness, and loss of weight Exophthalmos, tremor of hands, tachycardia, and enlargement of the thyroid gland were noted, and the B M R was + 47% Treatment with thiouracil 0 2 g b d was started on March 26 Clinical response was rapid, and thyroidectomy was done on May 24 In this patient, only calcium excretion in the urine was estimated, owing to difficulties of collection

Case 5—A contractor, aged 29, was admitted on Oct 10, 1949, with a history of recent diarrhœa and abdominal pain He was diagnosed as a case of severe hyperthyroidism, his B.M R. being + 90% He also had infected tonsils On Oct 17 his serum calcium was 11 05 mg per 100 ml, serum phosphorus 4 3 mg, and alkaline phosphatase 35 units Treatment with thiouracil 0 2 g t d s was started on Oct 21 The response was excellent and on Nov 20, iodisation was started as a prelude to thyroidectomy on Dec 7

Case 6—A male nurse aged 40, was admitted on Aug 15, 1949, after he had been diagnosed in March, 1947, as a case of thyrotoxicosis, his B M R then being + 55% He had been given thiouracil for 5 months with good results, but symptoms had recurred each time an attempt was made to stop giving the drug On admission he had had no thiouracil for 2 months, and he showed obvious signs of thyroid overactivity, his B M R on Aug 16 being + 30% He had also

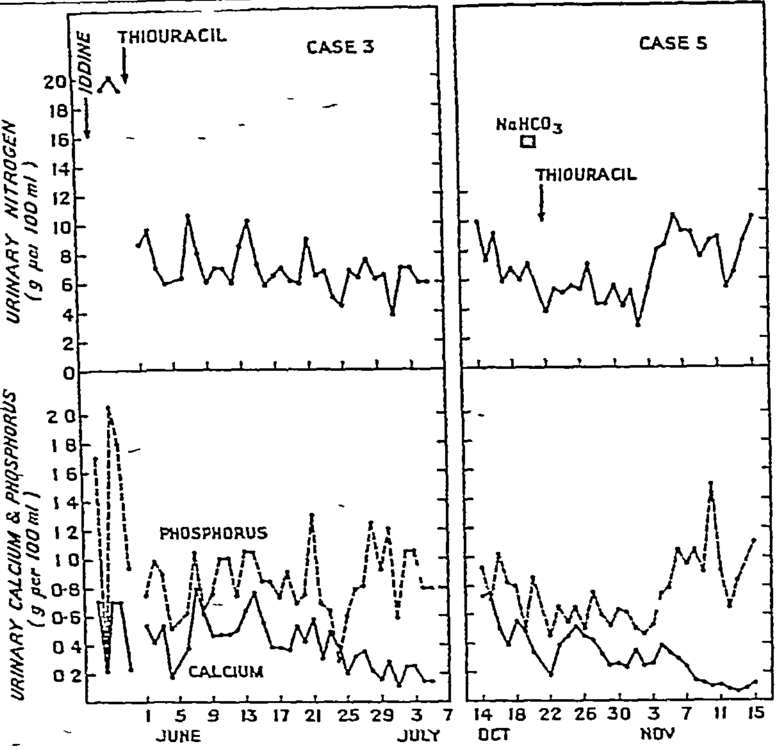

Fig 2—Urinary calcium phosphorus and nitrogen in cases 3 and 5

brief attacks of auricular fibrillation for a few days Treatment with thiouracil 0·2 g b d was started on Aug 22 and thyroidectomy after a course of iodine, was done on Sept 23

RESULTS AND DISCUSSION

The daily levels of urinary excretion of calcium, phosphorus, and nitrogen in our six cases before and during treatment are shown in figs 1–4 Grossly increased excretion of calcium before treatment is shown by cases 1–5, and in cases 1, 2, 4, and 5 a definite decrease in excretion of calcium is apparent about 7 days after the start of thiouracil treatment, and normal levels are attained in another 14 days. These results give more detailed confirmation of Lundbaek's findings (1947)

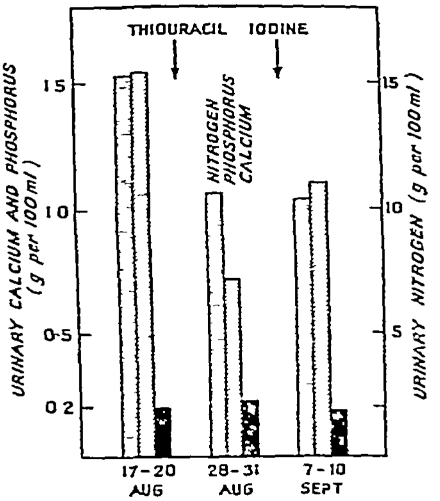

Fig 4—Urinary calcium phosphorus and nitrogen in case 6

In case 3 (fig 2) no significant downward trend occurs for 25 days, and levels below 0 2 g of calcium a day are not maintained for another 8 days One may speculate whether the delay in response to thiouracil clinical and biochemical, was due to the initial severity of the disease or to the preceding heavy dosage of iodine

These results throw little light on the origin of the increased excretion of calcium in hyperthyroidism If it were due to a direct effect of thyroid hormone on bone katabolism, one would expect it to show a closer relationship to the increase in B.M.R., and, if it derived from mobilisation of base to deal with the acidosis of protein katabolism, one would expect a closer relationship to the urinary excretion of nitrogen and phosphorus It is obvious from our data that grossly increased excretion of nitrogen and phosphorus is not necessarily accompanied by increased excretion of calcium, and vice versa

In case 5 two further studies were conducted with a bearing on possible theories fig 5 shows serum calcium and serum phosphorus levels, and urinary calcium levels and totals, before and during treatment If, as Robertson (1942) suggests, the increase in excretion of calcium is due to a direct action of thyroid hormone on renal clearance, there should be an inverse relationship between serum and urinary levels, as he implied In case 5 a direct relationship is shown, a high urinary level accompanying serum calcium and serum phosphorus levels on the high side of normal, a feature also noted in cases 1 and 2

We felt that the rejection by Albright et al (1931) of the hypothesis that disturbance of acid-base equilibrium might be significant was open to criticism Apart from the fact that their argument has an admitted teleological basis, acidosis in hyperthyroidism may be more complex than the loss of fixed base which they studied Ketosis may occur, but, in addition, the production of excessive amounts of carbon dioxide over long periods may strain the buffering capacity of the blood In that event the formula of Rona and Takahashi (1913) could be applied to derive the increase in calcium ions, and in similar situations it is known (Farquharson et al. 1931, Nelson 1928) that the increase in urinary excretion of calcium is out of all proportion to the drain on fixed base Accordingly case 6 was given sodium bicarbonate 10 g by mouth between Nov 19 and Nov 21 On Nov 22 his urinary calcium had fallen from the previous level of 24–38 mg to 8 8 mg per 100 ml. and his total excretion for the 24 hours to normal limits In view of possible chance variation this finding in a single person is not significant, but this aspect will be studied later

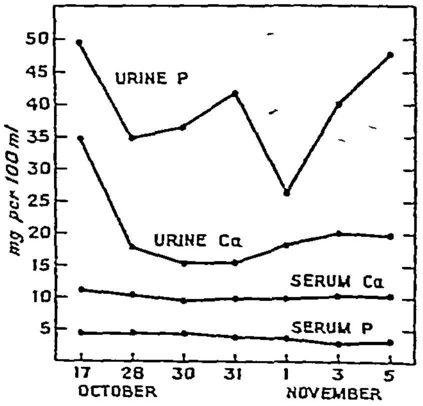

Fig 5—Serum-calcium serum-phosphorus and urinary calcium and phosphorus in case 5

SUMMARY

Six cases of severe hyperthyroidism have been studied before and during treatment with thiouracil

In four of the five cases showing excessive urinary loss of calcium diminution was observed about 7 days after the start of thiouracil treatment, and normal values were attained about 14 days later

The bearing of these and other data on the mechanism of the increased excretion of calcium in hyperthyroidism is discussed

Grateful acknowledgment is made to Sister M E Thomson and the residents and nurses of the metabolic ward, Aberdeen Royal Infirmary, for their coöperation in these investigations , and to Dr Ian Gordon for permission to use one of his cases

REPAIR OF THE CERVICAL TRACHEA AND LARYNX

EMLYN LEWIS
F R C S
SURGEON, PLASTIC SURGERY CENTRE, ST LAWRENCE HOSPITAL, CHEPSTOW, AND UNITED HOSPITALS, CARDIFF

IN view of the difficulties of reconstructing the trachea (see *Lancet* 1950), the following case is of interest

A boy, aged 16, was referred to the Plastic Surgery Unit, Gloucester, for closure of an opening into the trachea and larynx He had had diphtheria as an infant, and this had necessitated tracheotomy For lack of adequate history, it was assumed that secondary infection had occurred at the time of the tracheotomy, and that this infection had destroyed much soft tissue, the tracheal rings, and part of the thyroid and cricoid cartilages Many operations had been performed on his neck , but treatment, undertaken by Prof T P Kilner and Mr R Battle when he was 8 years old (with the object of restoring patency of the lumen above the tracheotomy) had been interrupted by the evacuation of the hospital in the early days of the war His condition before that treatment is shown in fig 1 , above the patent opening into the trachea a median slit communicated with the larynx After that treatment his condition was as appears in figs 2 and 3

Examination

The patient spoke in a whisper, which he achieved by pushing his chin downwards and backwards into his neck He was appalled by his condition and had attempted suicide He was doubtful of the prospect of repair and resistant to treatment In the midline of the front of his neck he had a large opening (fig 2) into his trachea this opening extended down to just above the episternal notch Above, it was estimated that five sixths of the rigid circumference had been lost, and below, it was regarded as tapering off to a loss of a third. At the upper end of the trachea was a transverse ridge (fig 2) which was thought to be made by the remains of the posterior inferior margin of the cricoid cartilage Above this ridge was a second opening (fig 2), which passed into the larynx Both openings were in a shallow pit in the front of the neck, the transverse ridge being more or less continuous with the plane of the skin From this it was assumed that the larynx and the upper end of the trachea had been drawn forwards by scar tissue The opening into the larynx admitted a no 9 endotracheal catheter, and the subglottic region was responsive to touch Direct examination of the larynx corroborated that it was drawn forwards The over all size was smaller than normal, the cords moved with respiration, and a no 7 endotracheal catheter could be passed between them and brought out through the opening in the neck

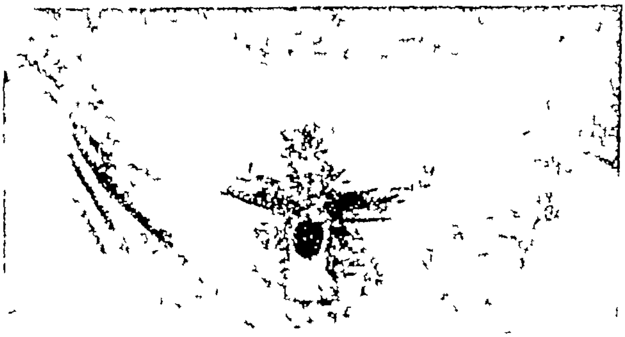

Fig 1—Condition of neck at age of 8 years before patient came under care of Professor Kilner and Mr Battle. A median slit above the tracheal opening communicated with the larynx.

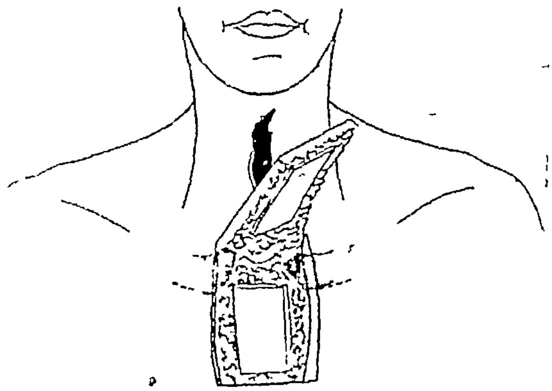

Fig 4—Delayed flap raised from manubrium and turned up to cover openings in neck.

Preparation for Treatment

The boy doubted his ability to breathe properly if these openings were closed by an operation To reassure him my dental colleagues constructed a soft acrylic collar which covered the openings and created an airtight lumen. This appliance worked admirably and convinced the patient of his power to breathe naturally, but it prevented him from pushing his chin downwards and backwards, and consequently he believed he could not speak However, Mr Robert Owen and I got him to make a guttural ‘ o ” sound , this we extended to “ Ee,” and later to “ Mary ” Finally, he could speak in more than a whispering tone, in fact he could shout By this time he had become more amenable to surgical repair

The broad requirements were for a rigid skin lining to cover both openings It had to be airtight, and covered by skin to avoid any raw surface on the outside

Surgical Repair

Treatment was carried out in five stages, some of them involving more than one procedure

Fig 2—Condition of neck at age of 16 after treatment by Professor Kilner and Mr Battle. Note scar tissue and transverse ridge

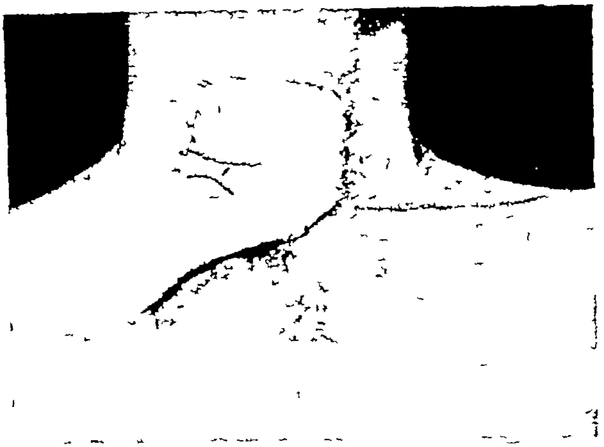

Fig 5—Tubed pedicle detached from left wrist opened for half its length to form a flap and stitched over delayed flap from manubrium Note raw surface on manubrium

Stage I (Oct 25, 1948)—A left abdominal tubed pedicle 4 in wide and 8 in long was prepared, to provide cover for the repair

Stage II (Jan 5, 1949)—The lateral end of the tubed pedicle was divided and attached to the radial border of the left wrist (fig 3) A delayed flap of requisite dimensions was made on the front of the manubrium and sternum (fig 3) The flap was based above the episternal notch and contained on its deep surface a sliver of bone and periosteum from the manubrium and sternum measuring roughly $1^1/_4$ in wide, $1^1/_2$ in long, and $^1/_{16}$ in thick

Stage III (March 24, 1949)—The medial end of the tubed pedicle was detached from the abdomen and implanted on the front of the chest at a selected site (fig 3)

Stage IV (May 5 1949)—Incisions were made on both sides of the openings in the neck and joined by a third incision across the neck above the opening into the larynx The incisions were undermined The delayed flap containing periosteum and bone was then raised from the front of the manubrium and sternum (fig 4), turned up to cover the openings in the neck and sutured to the medial margins of the incisions This flap provided the rigid skin lining Next the tubed pedicle was freed from the left wrist, and from this free end the pedicle was opened for a little more than half its length The flap formed by opening the pedicle was sutured into the lateral margins of the incisions in the neck, with the skin surface superficial (fig 5) It formed a cover flap for the rigid skin lining flap

Stage V (June 9, 1949)—The remaining tubed portion of the pedicle was detached from the chest wall, opened and fixed into the raw surface on the manubrium and sternum (fig 6)

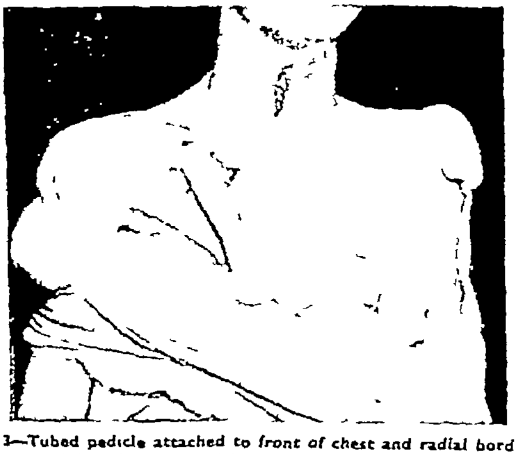

Fig 3—Tubed pedicle attached to front of chest and radial border of left wrist. Note delayed flap over manubrium.

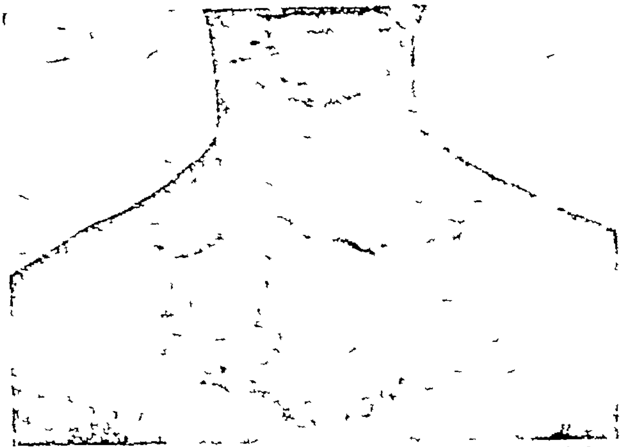

Fig. 6—Repair completed tubed pedicle has been detached from chest, converted into flap and fixed over raw surface on manubrium

The repair proved successful, and a year after completion of surgical treatment the boy was working as an electrician He spoke well, though his voice was slightly husky He could ride a bicycle and run without any difficulty in breathing He could expectorate satisfactorily There was no suction effect on the repair when he took a deep breath The sliver of bone in the neck could still be felt, was much the same in size as originally, and did not hamper movements of the neck

I am indebted to Professor Kilner and Mr Battle for fig 1

THERAPEUTIC EFFECT OF AN ALLERGIC REACTION TO FOOD ON RHEUMATOID ARTHRITIS

L G POLYMENAKOS
M.D Athens, L M.C Canada
FORMERLY SECRETARY GENERAL, MINISTRY OF HEALTH, TORONTO, ONTARIO

THE therapeutic success of Hench et al (1949) with 'Cortisone' and the adrenocorticotropic hormone (A C T H.) in rheumatoid arthritis indicates that most of the clinical manifestations of this disease can be reversed with the result that the patient feels well again, but the precise actions of the hormones are unknown

A C T H presumably acts by stimulating the adrenal cortex to secrete its hormones but the function and chemical composition of but few of these hormones are known We can separate some of them as glucocorticoids (e g, cortisone and 'Compound F') concerned in the metabolism of sugar, mineralocorticoids (e g, deoxycortone) concerned in the metabolism of sodium, potassium, and water, and the 17 ketosteroids and other steroids, whose actions are synergic with, or antagonistic to those of other endocrine glands, especially the gonads, and play an important part in the resistance of the body against disease

The observation that, in the synovial fluid of patients with rheumatoid arthritis, the concentration of hyaluronic acid and the activity of hyaluronidase are abnormal (Meyer 1947) has led to the suggestion that the enzymes which are responsible for the synthesis of glycogen might similarly play a part in the composition of hyaluronic acid, which is a similar polysaccharide, and probably contain or depend on the glucocorticoids, of which cortisone is one, for the synthesis of hyaluronates or other substances of the intercellular matrix This hypothesis, however, has not been proved

The results obtained by Hench et al (1949) and Thorn et al (1949) with cortisone and A C T H lend

The bearing of these and other data on the mechanism of the increased excretion of calcium in hyperthyroidism is discussed

Grateful acknowledgment is made to Sister M E Thomson and the residents and nurses of the metabolic ward, Aberdeen Royal Infirmary, for their coöperation in these investigations, and to Dr Ian Gordon for permission to use one of his cases

REPAIR OF THE CERVICAL TRACHEA AND LARYNX

EMLYN LEWIS
F R C S
SURGEON, PLASTIC SURGERY CENTRE, ST LAWRENCE HOSPITAL, CHEPSTOW, AND UNITED HOSPITALS, CARDIFF

IN view of the difficulties of reconstructing the trachea (see *Lancet* 1950), the following case is of interest

A boy, aged 16, was referred to the Plastic Surgery Unit, Gloucester, for closure of an opening into the trachea and larynx He had had diphtheria as an infant, and this had necessitated tracheotomy For lack of adequate history, it was assumed that secondary infection had occurred at the time of the tracheotomy, and that this infection had destroyed much soft tissue, the tracheal rings, and part of the thyroid and cricoid cartilages Many operations had been performed on his neck, but treatment, undertaken by Prof T P Kilner and Mr R Battle when he was 8 years old (with the object of restoring patency of the lumen above the tracheotomy) had been interrupted by the evacuation of the hospital in the early days of the war His condition before that treatment is shown in fig 1, above the patent opening into the trachea a median slit communicated with the larynx After that treatment his condition was as appears in figs 2 and 3

Examination

The patient spoke in a whisper, which he achieved by pushing his chin downwards and backwards into his neck He was appalled by his condition and had attempted suicide He was doubtful of the prospect of repair and resistant to treatment In the midline of the front of his neck he had a large opening (fig 2) into his trachea, this opening extended down to just above the episternal notch Above, it was estimated that five sixths of the rigid circumference had been lost, and below, it was regarded as tapering off to a loss of a third. At the upper end of the trachea was a transverse ridge (fig 2) which was thought to be made by the remains of the posterior inferior margin of the cricoid cartilage Above this ridge was a second opening (fig 2), which passed into the larynx. Both openings were in a shallow pit in the front of the neck, the transverse ridge being more or less continuous with the plane of the skin From this it was assumed that the larynx and the upper end of the trachea had been drawn forwards by scar tissue The opening into the larynx admitted a no 9 endotracheal catheter, and the subglottic region was responsive to touch Direct examination of the larynx corroborated that it was drawn forwards The over all size was smaller than normal, the cords moved with respiration, and a no 7 endotracheal catheter could be passed between them and brought out through the opening in the neck

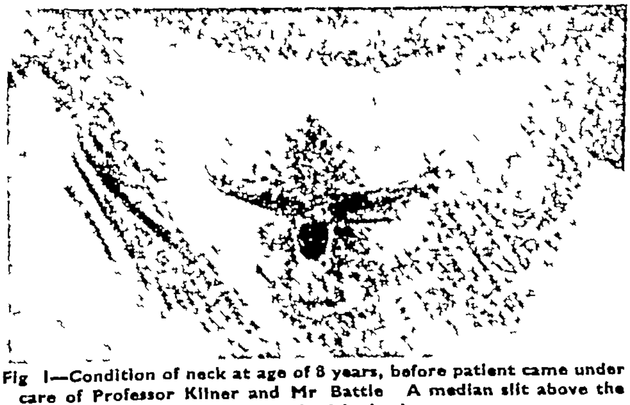

Fig 1—Condition of neck at age of 8 years, before patient came under care of Professor Kilner and Mr Battle A median slit above the tracheal opening communicated with the larynx.

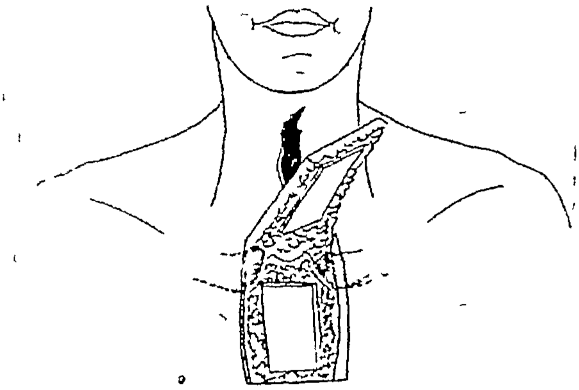

Fig 4—Delayed flap raised from manubrium and turned up to cover openings in neck.

Preparation for Treatment

The boy doubted his ability to breathe properly if these openings were closed by an operation To reassure him my dental colleagues constructed a soft acrylic collar which covered the openings and created an airtight lumen. This appliance worked admirably and convinced the patient of his power to breathe naturally, but it prevented him from pushing his chin downwards and backwards, and consequently he believed he could not speak However, Mr Robert Owen and I got him to make a guttural 'e" sound, this we extended to "Ee," and later to "Mary" Finally, he could speak in more than a whispering tone, in fact he could shout. By this time he had become more amenable to surgical repair

The broad requirements were for a rigid skin lining to cover both openings It had to be airtight, and covered by skin to avoid any raw surface on the outside

Surgical Repair

Treatment was carried out in five stages, some of them involving more than one procedure

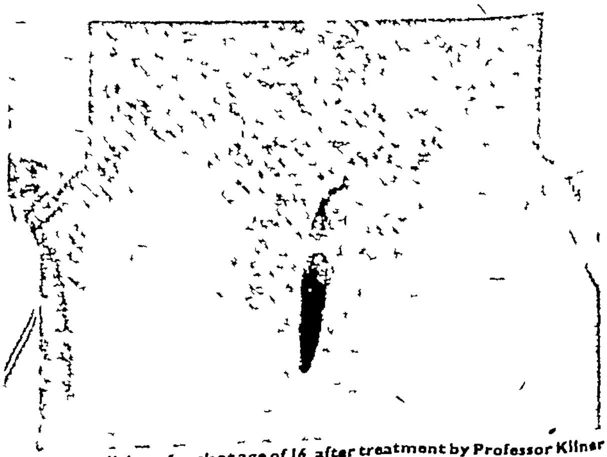

Fig 2—Condition of neck at age of 16 after treatment by Professor Kilner and Mr Battle. Note scar tissue and transverse ridge.

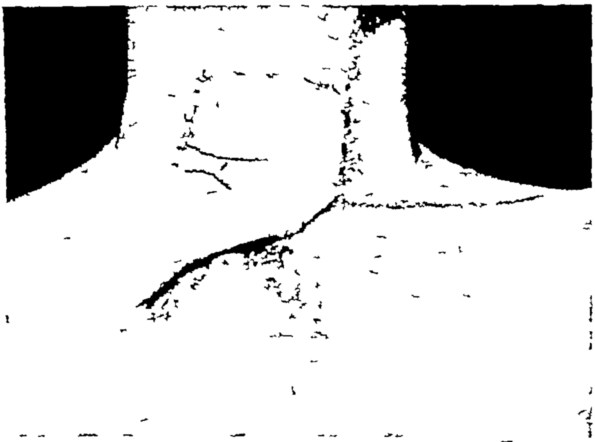

Fig 5—Tubed pedicle detached from left wrist opened for half its length to form a flap and stitched over delayed flap from manubrium Note raw surface on manubrium

Stage I (Oct 25, 1948)—A left abdominal tubed pedicle 4 in wide and 8 in long was prepared, to provide cover for the repair

Stage II (Jan 5, 1949)—The lateral end of the tubed pedicle was divided and attached to the radial border of the left wrist (fig 3) A delayed flap of requisite dimensions was made on the front of the manubrium and sternum (fig 3) The flap was based above the episternal notch and contained on its deep surface a sliver of bone and periosteum from the manubrium and sternum measuring roughly $1\frac{1}{4}$ in wide, $1\frac{1}{2}$ in long, and $\frac{1}{16}$ in thick

Stage III (March 24, 1949)—The medial end of the tubed pedicle was detached from the abdomen and implanted on the front of the chest at a selected site (fig 3)

Stage IV (May 5, 1949)—Incisions were made on both sides of the openings in the neck and joined by a third incision across the neck above the opening into the larynx The incisions were undermined The delayed flap containing periosteum and bone was then raised from the front of the manubrium and sternum (fig 4), turned up to cover the openings in the neck and sutured to the medial margins of the incisions This flap provided the rigid skin lining Next the tubed pedicle was freed from the left wrist and from this free end the pedicle was opened for a little more than half its length The flap formed by opening the pedicle was sutured into the lateral margins of the incisions in the neck, with the skin surface superficial (fig 5) It formed a cover flap for the rigid skin lining flap

Stage V (June 9, 1949)—The remaining tubed portion of the pedicle was detached from the chest wall, opened and fixed into the raw surface on the manubrium and sternum (fig 6)

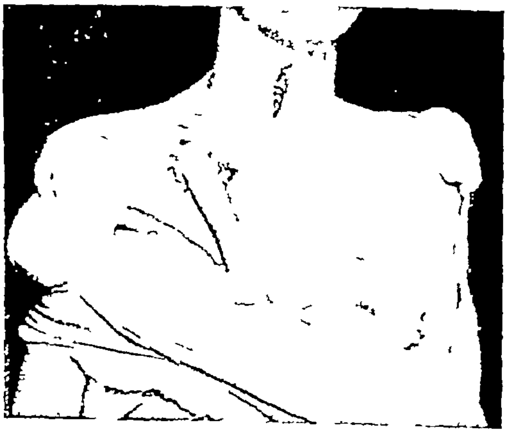

Fig 3—Tubed pedicle attached to front of chest and radial border of left wrist. Note delayed flap over manubrium

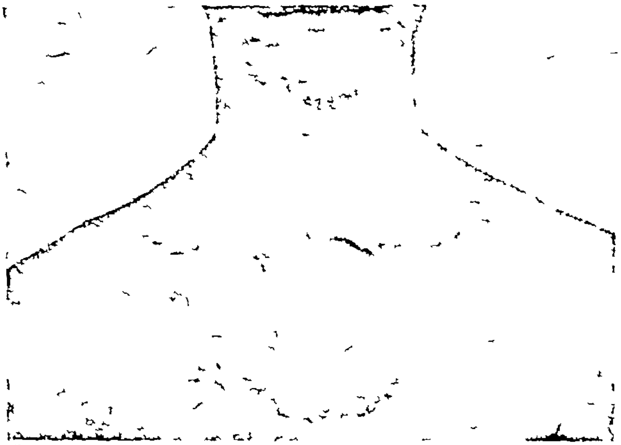

Fig 6—Repair completed tubed pedicle has been detached from chest converted into flap and fixed over raw surface on manubrium

The repair proved successful, and a year after completion of surgical treatment the boy was working as an electrician He spoke well, though his voice was slightly husky He could ride a bicycle and run without any difficulty in breathing He could expectorate satisfactorily There was no suction effect on the repair when he took a deep breath The sliver of bone in the neck could still be felt, was much the same in size as originally, and did not hamper movements of the neck

I am indebted to Professor Kilner and Mr Battle for fig 1

THERAPEUTIC EFFECT OF AN ALLERGIC REACTION TO FOOD ON RHEUMATOID ARTHRITIS

L G Polymenakos
M D Athens L M C Canada
FORMERLY SECRETARY GENERAL, MINISTRY OF HEALTH, TORONTO, ONTARIO

THE therapeutic success of Hench et al (1949) with 'Cortisone' and the adrenocorticotropic hormone (A.C T H) in rheumatoid arthritis indicates that most of the clinical manifestations of this disease can be reversed with the result that the patient feels well again, but the precise actions of the hormones are unknown

A C T H presumably acts by stimulating the adrenal cortex to secrete its hormones but the function and chemical composition of but few of these hormones are known We can separate some of them as glucocorticoids (e g, cortisone and Compound F') concerned in the metabolism of sugar, mineralocorticoids (e g, deoxycortone) concerned in the metabolism of sodium, potassium, and water, and the 17 ketosteroids and other steroids, whose actions are synergic with, or antagonistic to, those of other endocrine glands, especially the gonads, and play an important part in the resistance of the body against disease

The observation that, in the synovial fluid of patients with rheumatoid arthritis, the concentration of hyaluronic acid and the activity of hyaluronidase are abnormal (Meyer 1947) has led to the suggestion that the enzymes which are responsible for the synthesis of glycogen might similarly play a part in the composition of hyaluronic acid, which is a similar polysaccharide, and probably contain or depend on the glucocorticoids, of which cortisone is one, for the synthesis of hyaluronates or other substances of the intercellular matrix This hypothesis, however, has not been proved

The results obtained by Hench et al (1949) and Thorn et al (1949) with cortisone and A C T H lend support to the hypothesis that rheumatoid arthritis is one of the "diseases of adaptation" (Selye 1946) The following case record points in the same direction —

CASE RECORD

A man, aged 68, was examined on May 12, 1949, complaining of stiffness of the joints, with aching, pain, redness, swelling, and very limited function Chronic rheumatoid arthritis was diagnosed The patient's blood pressure was 170/95 mm Hg and the erythrocyte sedimentation rate was above normal His urine contained leucocytes and a few red blood cells He had a large prostate and frequency of micturition If he stood up suddenly he felt giddy Radiography showed rarefaction of bone and irregularity of bone surfaces

Treatment —The patient was given a good diet, low in sodium and excluding alcohol, and was ordered to rest Salicylate, iodine, and ascorbic acid were given by mouth in moderate doses To improve the anabolism of the bones, absorption of œdema in the joints, and the strength of the bladder, testosterone propionate 75 mg and thiamine hydrochloride 300 mg were given intramuscularly and 10% calcium gluconate 30 ml intravenously each week

Progress —The patient s condition improved until June 10, 1949, when I was urgently called to see him and found him with œdema of the eyelids and lips, dyspnœa, and itching He said that the previous evening he had had fish for supper, and that the present condition had come on soon afterwards All the symptoms were those of an allergic reaction to food Calcium gluconate, and ascorbic acid were given intravenously and 'Benadryl' by mouth and the patient was told to drink plenty of water When I next visited him I found that not only had his allergic condition improved but also he rose from his bed easily and no longer had any stiffness of his joints For the next five weeks the patient received the same kind of treatment as before but not so intensive A surprising amelioration of his rheumatoid symptoms was the result Six months after his allergic attack, he was still completely free from symptoms Both his hands had the capacity, movement, strength, and appearance of those of a normal person of his age

DISCUSSION

The treatment given in this case helped the patient, but the allergic reaction to food (fish) was the chief cause of the remission of the rheumatoid arthritis The clinical improvement began only fifteen hours after the allergic reaction, and, although the previous treatment was continued, though less intensively, for only five more weeks after the allergic attack, the improvement was very speedy and progressive until complete remission of the disease

The improvement can be explained in terms of the general adaptation syndrome of Selye (1946) The endocrine mechanism came into action because of the excessive stress of the allergic attack, which was an effective stimulus for the production of the "alarm reaction" including increased adrenocortical activity During the alarm reaction an excess of A C T.H can be demonstrated in the blood (Ungar 1944), and the production of adrenal corticoids (e g, cortisone and compound F) is increased, thus augmenting the non specific resistance of the organism

If this explanation is correct, the result in the present case was similar to those obtained by the use of cortisone and A C T H as described by Hench et al (1949) and Thorn et al (1949)

Preliminary Communication

RADIOGRAPHY IN COLOUR

X RAYS and light are both electromagnetic radiations, but the wave lengths which stimulate the retina (visible spectrum) range from about 3200 to 7500 Ångstrom units * (Å) whereas the X ray spectrum extends from 0 06 to 500 Å, the X rays used in diagnosis being those between 0 128 and 0 414 Å

The "hardness" of an X ray beam depends on its wave length, the hardest rays having the shortest wavelengths, so hardness is closely analogous with colour in a beam of light Raising the kilovoltage passing through the X ray tube shortens the wave length and increases the hardness of its X ray emission—e g, a boundary wave length of 0 414 Å is equivalent to a peak tension of 30 kV, and a wave length of 0 138 Å to 90 kV The penetration of X rays through a given substance depends on their hardness, the short hard rays being most penetrating, on the density of the substance, and on the atomic numbers of the elements of which it is composed Thus by varying the kilovoltage (wave length) of the X ray beam, and therefore its penetrating power, we can take a series of pictures of a part of the body each emphasising different details—for example, if we take two X ray films of the head, one with 45 kV and the second with 90 kV peak tension, the first will show the soft tissues, and the second the bony structure

THEORY

The basis of the three colour theory of colour vision is that all colours, including white, can be matched by mixing the three "primary" spectral colours This premise is not strictly true, for the match is not exact, the colour to be matched, as seen in the solar spectrum, is almost always noticeably more "saturated" than the mixture which imitates it Nevertheless, applications of the theory give good results in practice and almost all natural colour photography is based on it By mixing only two primary colours one can get a more limited range of colour effects, which will be satisfactory for many purposes and may greatly simplify the technique

Colour radiography has something in common with the staining or "tagging" practised in microscopy, as well as with colour photography

Additive Method

A composite picture in pseudo natural colour can be produced by projecting positive films or positive transparencies of three radiograms on to a viewing screen at the same time The positive of the radiogram taken at the lowest kilovoltage can be tagged by projecting it with light of a primary colour, say red, the one taken at the medium kilovoltage with green, and the one at the highest kilovoltage with blue If a more limited spectral range seems sufficient, two films and two primary colours are used A similar effect can be obtained with a chromoscope, in which the three films are illuminated with light in the three primary colours, as before, and are then optically superimposed by the use of partly transmitting and partly reflecting mirrors to form a composite coloured picture

Subtractive Method

Before it can be published, the composite colour radiogram must of course be in the form of a colour print on paper The easiest way to obtain such a print is to treat the radiograms taken at the various kilovoltages as if they were the colour separation negatives of colour photography, and to restrict oneself to two colours I have used a modification of the trichrome carbro process, and the two colours chosen were cyan blue and yellow The composite colour print is made by a "subtractive" method This depends on the filtering, absorption, or subtraction of appropriate amounts of the three primary colours from white light as it passes through the two superimposed colour images to the white paper support and is reflected back again through the colour images. For instance, the cyan blue image absorbs the red rays but reflects the blue and green, whereas the yellow image absorbs the blue but reflects the green and red. Each colour image acts as a colour-filter for the other. This combination gives a composite picture in colour of a limited but satisfactory spectral range. By using an additional image printed in magenta, which absorbs green rays and reflects red and blue, the spectral range can be widened considerably.

---

* The Ångström unit of wave length is a ten millionth of a millimetre (10^{-7} mm.) and a tenth of a millimicron (0 1 mμ)

The rendering of colour on a paper colour print always falls far short of perfection. The trichrome carbro process is among the most popular and most difficult of the indirect processes for making composite colour prints on paper. Very beautiful composite paper colour prints have been made by "subtractive" methods, but their cost and complications have restricted their practical use to a few professional and a very few advanced amateur photographers.

TECHNIQUE

The patient must keep quite still while all the X-ray exposures are made. One must get his complete confidence and coöperation by explanation and reassurance beforehand, and see that he is comfortable and relaxed. The recognised methods of the skilled radiologist are used to control unwanted respiratory movement, involuntary swallowing, &c. When some parts are to be examined—e.g., head and neck—the patient must immobilise not only the whole parts but also their components such as the mandible and tongue. Mechanical restraint is sometimes useful here. Needless to say, the radiologist must not waste time over his manipulations.

Markers opaque to X rays should be attached to the part being radiographed, so that indication marks appear on the films. This facilitates exact registration in making the composite colour print. The colour separation positives are adjusted over one another so that the points at which they register are clearly seen.

CONTRAST

The scale of densities in an X-ray negative film is greater than in a photographic negative film. The effective photographic range in black-and-white photography is about 1 to 128. Various factors affect the contrast in an X-ray film, such as the length of exposure, the wave-length of the beam, the scattering of the beam (diffusion), and the type of intensifying screen.

Monochrome photographic film technique depends on light and tone contrast, whereas colour films depend on colour contrast. Colour-film photography is unsuitable for objects with unusual amounts of contrast, and it is then for the photographer to decide whether the shadows or high lights shall be lost. It is understandable that the *orthodox colour photographers prefer* comparatively flat positives.

The contrast range in orthodox colour photography is only 1 to 4. It should be *emphasised* that the eye is much more sensitive to differences in colour than in brightness. The best method of colour radiography is the projective or chromoscopic one, which gives a nearly perfect contrast range, because the greatest loss occurs in making the composite colour print. It would probably be better to use X-ray negatives rather than positives, because as a rule the negatives seem to be more informative.

CONCLUSIONS

A colour radiogram presents its information in an attractive form. In one picture it can convey the information of two or more orthodox radiograms. The total effect is something more than that of the component radiograms. The method shows variations not only in density but also in colour, and the variations in colour may ultimately prove the more important.

Colour radiography will be valuable in studying the details of soft tissue, because it differentiates between degrees of softness inside the tissue as well as defining its outline. When three monochrome radiograms of the soft tissues of a limb are taken at 30, 32, and 34 kV there is a recognisable difference in the details they bring out, and the difference will be usefully accentuated in a composite colour *radiogram made from them*. The same principle applies in the medium and hard X-ray bands.

There are no insurmountable difficulties in the way of developing a single-exposure method of colour radiography. Movement of the patient could be prevented by making the exposures in rapid succession with a mechanism adapted from that of serial radiography or direct cineradiography. By means of a mechanical or electronic device, or a combination of both, the kilovoltage and milliamperage of the X-ray tube could be adjusted automatically and serially. These methods could also be followed with an indirect cineradiographic technique.

Colour stereoradiography, colour fluoroscopy, colour stereofluoroscopy, colour cineradiography, and colour stereocineradiography are all possibilities for the future.

Colour radiography should stimulate research and have value in diagnostic radiology and other branches of medicine. It is now only in its infancy. Its ultimate value will depend on the ability and enthusiasm with which it is pursued. Research-workers in this field should have a first-class knowledge of physics, especially of electronics.

I wish to thank Dr Glyn Jones, consultant radiologist, Swansea General Hospital, for making the X-ray negatives *and for his helpful advice and criticism*.

Medical Societies

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

THE annual congress was held at the Royal Society of Medicine from March 29 to 31, under the presidency of Mr MAURICE H. WHITING. Among the visitors officially welcomed at the opening session were Prof. J. François (Ghent), Dr John D. Blum (Geneva), Dr Noelle Chomé (Lausanne), and Dr P. Mendoza (Philippine Islands).

PRESIDENTIAL ADDRESS

Having chosen Rodent Ulcer as the subject of his presidential address, Mr Whiting was able to draw on his own extensive experience at the Middlesex Hospital for the last quarter of a century. During that period, he said, reports on 1000 sections of rodent ulcer were issued by the Bland Sutton Institute of Pathology, and it was interesting to note that 95% were situated on the face and head, and of these approximately 65% were found adjacent to an eye. In other words more than 60% of all rodent ulcers threaten sight.

Mr Whiting's main thesis was that in properly selected cases, surgical removal is preferable to radiotherapy. He laid stress on the importance of histological examination with a view to differentiating the circumscribed from the infiltrating type of growth, and stated that the chief value of radiotherapy is in the infiltrating variety. Of his series, 81% were cured by surgery at the first attempt, and the percentage of finally uncured cases was only 11, failure being amply explained by the size and perhaps not often enough The terminology used is the B N A. with some lapses, more particularly in the index, where the dura mater encephali is listed both as such and under "brain, hard membrane of" The labelling is always clear, though the script used is sometimes rather fussy and obtrusive Nearly twice as many pages of figures are devoted to the abdomen and pelvis as to any other region, and the series of plates on the female pelvis and perineum, and those on the anterior abdominal wall and inguinal region, are outstanding There are some defects in emphasis the joints are in general rather perfunctorily illustrated, mostly by diagrams from other sources, the eye and orbit are treated in much less detail than the ear, and the tonsil is relatively neglected Most of the variations shown statistically are of importance to the medical graduate (such as those of the appendix, the cystic artery, and the level of termination of the spinal cord), but some are not (including those of the palmaris longus and the pyramidalis muscles) On the other hand, aberrations of many notoriously variable and important structures are not given, thus variations in the nerve-supply of the hand, or in the mode of formation of the brachial plexus, are ignored, and indeed, the main defect of the atlas is that the peripheral nerves, particularly of the limbs, are inadequately figured and their branches inadequately labelled The cutaneous nerves in particular are almost completely neglected, and readers will look in vain for the sural nerve, or for any indication that the obturator nerve, though it appears in some 18 illustrations, has any cutaneous or articular branches The atlas is beautifully produced and bound, and despite the scope of its contents is both portable and convenient to consult

Eternal Eve

HARVEY GRAHAM London Heinemann Medical Books 1951 Pp 699 42*s*

HERE is a book on a subject recognised as "news" The author describes it as the story of women from the Stone Age until today—Myth, Magic, and Medicine—but in fact it is the history of midwifery and everything connected with it, among primitive peoples, in Ancient Greece, Rome, and Byzantium, in the Middle Ages, and so down to the present As we come to more recent times we see clearly the interplay of each new scientific advance in the management of labour The author's knowledge of the by-ways of his vast theme never fails him, and he moves easily in the historical background of the changing scenes from age to age The lying-in chamber dominates the book, though most women will feel that the few hours spent there, during a lifetime, hardly deserve such close, and even gross, attention from a biographer The scholarship and literary skill of the author are beyond dispute, and, this task done, may now perhaps be freed for more attractive uses The section on the modern management of labour shows that his power of engaging his reader's attention need owe nothing to the morbid

Advances in Carbohydrate Chemistry—Vol V

CLAUDE S HUDSON, National Institute of Health, Bethesda, Maryland, SIDNEY M CANTOR, American Sugar Refining Co, Philadelphia New York Academic Press 1950, Pp 322

THESE monographs dealing solely with carbohydrate chemistry are a product of the age of specialisation, but the Anglo-American editors, and the authors, who have been drawn from the United States, Great Britain, and the Commonwealth, have done their best to fulfil the promises made with the first volume—to provide 'critical and integrating reviews, intelligible to the average chemist rather than only to the specialist" The 10 articles in this volume deal with biochemical as well as chemical topics, and the former are more directly of interest to doctors There is a very clear account of the enzymatic synthesis of sucrose through α-D glucose-1-phosphate (the Cori ester) and fructose The fructose apparently does not combine directly with the enzyme and can be replaced by xyloketose or sorbose with the formation of the corresponding non-reducing disaccharides There is an article on enzyme specificity in the domain of carbohydrates, and others on pectases and α-amylases There is a review of the methyl ethers of glucose which have played such a large part in establishing the constitution of this and all the other sugars. The account of the commercial production of crystalline dextrose is likely to interest some doctors, for we must be among its largest users The history of the process, which goes back 150 years, well illustrates how war and the laws of economics will at times interact to produce some highly desirable material The article on xylan makes one wonder whether this substance may not replace inulin or dextran in physiological work, its preparation presents no greater difficulties In short, formidable though some of these articles appear—for example, the one on reductive desulphurisation by Raney nickel, or the one on the anhydrides of the pentitols and hexitols—the book contains much valuable information for advanced students and teachers Probably they will borrow it from a library, but the worker on carbohydrate metabolism will want it for his own bookshelf

---

A Textbook of Gynæcology (8th ed London Adam & Charles Black 1951 Pp 493 40*s*)—A fresh edition of Prof James Young's book follows hot on the heels of the last, but in three years there has been much news among the gynæcologists, particularly on the subject of tumours Besides enlarging this section substantially, he has revised the whole text and added 17 illustrations including a coloured plate

Color Psychology and Color Therapy *A Factual Study of the Influence of Color on Human Life* (London McGraw Hill 1950 Pp 284 42*s* 6*d*)—This book is evidently the outcome of much searching in libraries, but Mr Faber Birren seems incapable of separating wheat from chaff, and unaware of the scientific background of the subjects treated in his discursive survey Thus he quotes Gurewitsch's work on mitogenetic radiations as though it had not been discredited, and he often startles the reader by putting the findings of serious workers beside the vapourings of quacks and cranks The theme requires a more critical approach

An Addendum to "King's and Some King's Men" (London Oxford University Press 1950 Pp 201 30*s*)—This, as the title explains, is a postscript to Dr Willoughby Lyle's exhaustive book on King's College Hospital and its medical school The original volume dealt with the period 1835–1934, and the object of the addendum is to complete the history of the voluntary hospital period, and bring it up to the day when the National Health Service took over the hospital and when the school became independently incorporated under the wing of the University of London. Like its predecessor the book is divided into chapters dealing with the events and personalities of successive years, with additional chapters on nursing, almoners, physiotherapy, and the like There is also a chapter on the Hambleden family, which did so much, in successive generations, for the hospital and school

The account of nursing is particularly instructive few, even of King's men, have remembered that before the Crimean War Florence Nightingale was invited to come to King's and reform the nursing arrangements, or that, even earlier, in 1848 it was four members of the honorary staff of King's who, with the Bishop of London, founded St John's House for the training of nurses, a move which had far reaching effects By relating what happened in the hospital with what happened in the outer world, Dr Lyle has produced a work of general interest, and the same thing could usefully be done for other hospitals and schools After all, it was the county histories, and researches into abbeys and manors, that built up so much of modern archæology and of the known history of England Small beer can be condensed into strong and satisfying liquor

Dr Lyle is to be congratulated particularly on two things his accuracy and his objectivity A historian is expected to be accurate, but the expectation is not always fulfilled, and when a mass of minute detail is found to be completely trustworthy, one cannot help being grateful (The only questionable statement observed was that Mrs Gamp was addicted to whisky surely it was gin ?) His objectivity is olympian, and his generosity to persons for whose memory he has little personal reason to be tender is splendid The book altogether is the crown of a great achievement

THE LANCET

LONDON SATURDAY, APRIL 14, 1951

Ætiology of Diabetes

THE concept that all types of human diabetes arise from disease of the pancreas originated in CAWLEY's paper of 1788[1] and was greatly strengthened by the findings of VON MERING and MINKOWSKI[2] in pancreatectomised dogs a century later The work of OPIE[3] in 1901 and of SSOBOLEW[4] in 1902 further localised the essential morbid process to the islets of Langerhans, and prepared the way for the discovery of insulin by BANTING and BEST More recently the picture has been complicated by the studies of extrapancreatic diabetogenic influences, such as those of the anterior pituitary, adrenal cortex, and thyroid gland, and in consequence diabetes is in danger of being degraded from its former position of a clinical entity to that of a mere syndrome with multiple causes

How far is this change of view justified ? According to WILDER,[5] less than 9% of the acromegalics seen at the Mayo Clinic were also diabetics, and in half of these the diabetes had clearly preceded the acromegaly , the diabetes usually disappeared when the acromegaly was treated or burnt itself out It seems then that in animals growth hormone can produce permanent diabetes,[6] but that it is never present in sufficient quantities in man, even when he is an acromegalic, to produce a lasting diabetes, unless perhaps in exceptional cases of genetic predisposition Temporary diabetes can also be produced in normal man by A C T H.,[7] but the diabetogenic potency of this hormone cannot be very great, since diabetes is a rare complication of its clinical use, though almost all the other manifestations of Cushing's syndrome are not uncommon as complications A third pituitary hormone—prolactin—has lately been shown to have diabetogenic properties,[8] but, like growth hormone and A.C T.H., this seems unlikely to cause permanent diabetes in man. Adrenal cortical diabetes is fairly easily distinguished from pancreatic diabetes, if only because it is insulin resistant and does not occur in a lasting form except in association with the other features of Cushing's syndrome Removal of the over-functioning adrenal tissue cures the diabetes In thyrotoxicosis it is not uncommon to find slight glycosuria and a high blood sugar curve, which cannot be entirely accounted for by over-rapid intestinal absorption, though this is present The formation of glycogen is delayed, and as a result high blood sugar curves are obtained even in intravenous glucose-tolerance tests These defects disappear, however when the thyrotoxicosis is controlled The rare cases of hyperglycæmia resulting from brain injury are not likely to be confused with pancreatic diabetes, for the high blood-sugar depends on the stores of glycogen in the liver and is therefore transient

Thus, though in animal experiments large doses of the hormones of the anterior pituitary, adrenal cortex, and thyroid gland have produced permanent diabetes or metadiabetes, there is no convincing evidence that they have done so in man This implies that man normally has such a large reserve of islet-cell function that he can respond to the extra load imposed by acromegaly, Cushing's syndrome, or thyrotoxicosis without exhausting his beta-cells, in the way characteristic of metadiabetes in animals WILDER[5] suggests that metadiabetes may still be the commonest human type, if obesity is regarded as the load which eventually overwhelms the responsive power of the beta-cells STETTEN and BOXER[9] have shown that normally dietary glucose is largely converted into fatty acids before being katabolised in the body, and that this conversion mainly depends on insulin. Thus obesity puts extra work on the pancreatic islets, quite apart from the increased metabolic requirements of the superfluous tissue As in experimental diabetes, early removal of the cause may allow carbohydrate tolerance to return to normal, but after many years of obesity the diabetes may persist, even though the person's weight eventually returns to normal. Since only a minority of fat people eventually develop diabetes, one must assume that, in addition to the diabetogenic effect of obesity there is an inborn meagreness of the reserves of islet-cell function. Opponents of the single (pancreatic) origin theory of diabetes point to the many necropsy reports on diabetics showing histologically normally pancreatic islets

In more than a quarter of WARREN's[10] 259 diabetic pancreases the islet tissue was essentially normal, and ROBBINS and TUCKER[11] found pancreatic lesions in only a little over 40% of their 184 necropsies on diabetics TERBRÜGGEN,[12] on the other hand, with his newer staining methods, has noted that 80% of human diabetics have abnormally small pancreatic islets containing relatively few beta-cells and disproportionately many alpha-cells Thus, as finer techniques reveal smaller variations from normal in islet-cell appearances, the unexplained gap is narrowing Abnormal function is perhaps not always associated with abnormal structure , but it is well to remember that in all the experimentally produced forms of metadiabetes definite structural changes were seen in the beta cells The evidence points to these changes of structure being caused by hyperglycæmia rather than by the inciting agent of the diabetes, for hyperglycæmia alone has produced permanent pancreatic diabetes in partly depancreatised cats—even in one normal cat[13]—and in diabetes induced with A.P E (anterior pituitary extract) phlorizin cures the diabetes and reverses the degeneration in the beta-cells,[14] presumably by lowering the blood-sugar. Another unifying concept in the ætiology of diabetes is the rôle of the glutathione in the blood and beta-cells in protecting the pancreas from various diabetogenic agents. Lazarow[15] found that glutathione administered before alloxan inhibits or prevents its diabetogenic effect, and that the susceptibility of animals to alloxan varies inversely with the glutathione levels[16] in their blood and tissues. Alloxan is rapidly reduced in the body to the relatively innocuous dialuric acid. The particular susceptibility of beta cells to the action of alloxan may be due to the higher O/R potential in these cells which must build S–S bridges in the insulin molecule (12% of which is cystine) from —SH compounds. Thus a high rate of insulin formation is likely to deplete the glutathione of the beta cells. Uric acid, which has been used to produce diabetes in rabbits deficient in thioamino acids,[17] is structurally related to alloxan. It is significant then that A.C.T.H. both increases the production of uric acid and lowers the blood-glutathione level. A.P.E. also lowers the glutathione content of the tissues. Thiouracil, which raises the blood glutathione level, prevents rats which have been 95% depancreatised from developing diabetes. Lazarow,[18] however, has introduced a jarring note by producing glycosuria in force-fed animals by injecting them with glutathione. In the concentrations he used, the glutathione may have partly reduced the S–S linkages of the animals' insulin, thus inactivating it.

The main impression gained from the more recent work on human diabetes is that it nearly always arises in the pancreas, and that obesity is the commonest predisposing factor, though it produces the disease only in people with a naturally inferior islet-cell reserve.

The Body's Iron

Two years ago Granick[19] outlined present knowledge of iron metabolism—a field in which he has done much original work. For a man weighing 70 kilogrammes the total iron in the body is between 4 and 5 grammes; 60–70% of this iron is in hæmoglobin, 3–5% in the myoglobin of muscle, 15% as ferritin, 0.1% as siderophilin, and 0.1% in hæm enzymes such as cytochrome, while about 10% is not accounted for.

Siderophilin and ferritin are comparatively new names and need explanation. Siderophilin is a pseudoglobulin protein molecule that can carry iron; oxygen oxidises ferrous to ferric iron, and in the presence of CO_2 a complex of one CO_2 molecule for each ferric atom is attached to the protein molecule. In the presence of reducing substances the ferric iron changes to ferrous and becomes detached from the protein. All the serum-iron is normally carried by siderophilin. Ferritin is a remarkable substance discovered thirteen years ago by Laufberger; it is a protein containing up to 23% of iron, and it is crystallisable because the protein part (apoferritin) is crystallisable. Ferritin can be isolated from many tissues, and especially liver, spleen, and bone marrow. It has two vital functions: it is the normal iron storage protein of the body; and it is a link in the absorption of iron from the alimentary tract and probably in the passage of iron across the placenta from mother to fœtus. Hæmosiderin, the microscopically stainable iron seen in histological sections, is a polymerisation product of ferritin but is not a normal storage form. The most important function of ferritin is connected with the regulation of iron absorption. Iron is only absorbable in the ferrous form; the stomach acid converts the colloidal ferric hydroxide of foodstuffs into monomolecularly dispersed ferric ions which at pH5 (but not at pH7) can be reduced to the ferrous form by ascorbic acid or the sulphydryl groups of protein foods. Tracer studies have shown that although iron can be absorbed along most of the gastro-intestinal tract, it is normally almost all absorbed from the duodenum just below the pyloric sphincter—i.e., in the area where the pH remains about 5. When large amounts of iron, such as therapeutic doses, are taken, the area of absorption spreads perhaps over the whole alimentary tract from stomach to large bowel. Nevertheless, there is, as we have explained,[20] a definite early limit to the amount of iron that can be absorbed. Repeated experiments have shown that the passage of iron across the intestinal mucosa is one-way only, and that the amount of iron passed from the alimentary tract into the blood depends on the presence and extent of anæmia. The intermediary substance probably responsible for this regulatory mechanism is ferritin, and Granick suggests the following hypothesis. When the ferrous iron passes across the intestinal cell, it is converted by the cell enzymes, in the presence of oxygen, into ferric iron and is then attached to apoferritin to form ferritin. At the blood-stream end of the cell, reducing substances in the cell reconvert the ferric to ferrous iron so that it becomes detached from the ferritin and passes out into the blood, to be taken up by the siderophilin for transport. The limiting factors are two: (1) the amount of apoferritin is limited, and once it is all converted to ferritin no more iron can be conveyed across the mucosa until some of the ferritin gives up its iron to the blood; and (2) the rate at which ferritin releases its iron depends, not on the level of serum iron, but on the oxygen supply at the blood-stream end of the cell, and this is only low enough to permit rapid transit when anæmia is present. Possibly the ferritin-apoferritin mechanism is not the sole controlling factor; there is quite a lot of evidence[21] that a diet containing excess phosphate may impede iron absorption. Such a diet would be rich in foods like meat, fish, and dairy products; so in this country, under present conditions, excess phosphate is unlikely to be troublesome.

Proper understanding of iron metabolism and of the steps in iron absorption is important to the physician. Iron-deficiency anæmia must be one of the commonest diseases in women, and it is more common in men than is supposed. The work on iron metabolism has shown that large oral doses are best, but that it is useless to give more than gr. 30 (2 g.) daily of ferrous sulphate; and that ascorbic acid aids absorption of the iron in protein foods. It is clear, too, that the iron-absorption mechanism efficiently protects the body against excessive absorption of unexcretable except in hæmochromatosis The introduction fective iron preparations for intravenous use has got round the protective absorption barrier, the question whether continued intravenous inistration may be harmful has been raised We that in patients with hæmolytic or aplastic mia who have received multiple blood-trans- ons, large amounts of iron are found deposited, e form of hæmosiderin, in the liver and spleen, in the liver may induce fibrosis and damage mbling that seen in spontaneous hæmochroma- ;[22] Might not intravenous iron do the same sort hing ? NILS ANDERSSON[23] has tried to answer question. - He gave to rabbits a standard intra- ous iron preparation in doses varying from 12 to mg Fe per kg body-weight In man the average l dose for anæmia is 1500–2500 mg Fe, or about ng per kg ANDERSSON's figures show that at this l the iron content of the liver and spleen fourteen s after injection was about four times normal, and t two to three months later it was still twice normal greatest absolute amount of iron was in the liver, weight-for-weight the spleen contained the most se increases are not very large, and the iron level the organs fell steadily after the injection at an rage rate of 0·13 mg per day Histological examina- n of the tissues showed a most interesting redistri- tion of the injected iron. In the liver it was at first en up by the Kupffer cells, after a week, however, iron staining was diffused in the cells of the liver enchyma, and pari passu the iron in the Kupffer ls diminished. Similarly, in the bone marrow the n was at first seen in the endothelial cells of the usoids, but later passed to the stroma Iron posited in the lungs gradually disappeared in two eks when a dose of 12 mg per kg was given, no n could be shown histochemically in the liver after e month, and last of all it disappeared from the leen and bone-marrow Where this iron goes to not clear, but experiments with radioactive iron ve shown that excretion of iron in the bile is creased from about thirty days after a parenteral se ANDERSSON also found that the iron in the bile his rabbits was increased about three times of CARL MOORE[24] has stated that the excretion iron is probably greater than has been suspected d he puts the figures at 1 mg Fe daily for en, and at 1·5 mg daily for women of menstrual e The suggestion that iron can be lost in the eat has now been denied, but iron is lost rough desquamated skin cells[25] In order to t toxic reactions from parenteral iron, ANDERSSON d to give about ten times the therapeutic dosage, s conclusions were confirmed when he examined the gans of a patient who had met with a fatal accident x weeks after completing a course of 800 mg of travenous iron No histochemically demonstrable on was present in the liver, spleen, or kidneys NDERSSON's work then, supports the view that arenteral iron in the present dosage—about 25–40 mg e for each 1% (0·148 g per 100 ml) hæmoglobin eficit—is quite safe and unlikely to cause permanent eposition of hæmosiderin

There have now been many more reports of the therapeutic use of intravenous iron HORRIGAN et al.[26] in the U.S.A confirm that, if single doses are limited to 100 mg Fe, reactions are few SINCLAIR and DUTHIE[27] record 51 cases of rheumatoid arthritis, none of which had responded to oral iron, intravenous administration gave a good result in 38 cases, but in 13 the hæmoglobin remained low In our columns SCOTT and GOVAN[28] have lately reported results in 150 cases of anæmia during pregnancy and the puerperium, they used intravenous iron especially for obtaining a rapid rise of hæmoglobin in pregnant women when time was short, and they, too, regard 100 mg Fe as a safe upper limit for single doses Despite these favourable results, there are some dangers with intravenous iron BIRCH and TILL[29] have described a case in which the patient developed iron encephalopathy—fortunately not fatal—after receiving altogether 380 mg Fe, the maximum single dose being 75 mg Consequently parenteral iron should not be used as a substitute for oral iron Many patients will respond to adequate doses of oral ferrous sulphate, especially if given in enteric coated tablets to prevent the troublesome gastric disturbance Not until this has failed should parenteral iron be used, the only ground for exception is need for a speedy response, as in pregnancy Repeated courses of intravenous iron are hardly ever necessary With proper precautions, this is a valuable method, and ANDERSSON's results make it clear that the bogy of artificially induced hæmochromatosis need not hamper its use

Tissue Culture and Biophysical Research

FEW biological techniques have experienced such fluctuations of fashion as tissue culture In its early days it was exalted almost to the status of a separate science, and such was the elegance of the method and the beauty of the material it produced that more and more people learned to grow cells though they had no particular object in view and had little knowledge of cell biology Papers on the subject became so numerous as to induce a sharp reaction against tissue culture, which led to some notable contributions being overlooked Today, however, thanks to the energy and enterprise of the few American workers who in 1946 founded the Tissue Culture Commission —now the Tissue Culture Association—the technique has been restored to an important position in medical and biological research The years of partial eclipse have had a salutary debunking effect, and tissue culture is taking its rightful place in laboratories as a very valuable experimental method with special advantages and special limitations Tissue growing in vitro has no vascular or nerve-supply and is isolated from the influence of adjacent structures and of the body as a whole, and this is one of the main advantages of the method For this reason however, experiments in vitro can rarely be substituted for experiments in vivo but should be used in conjunction with them For example, if one wants to analyse the complex reactions of the body to some therapeutic agent, such as radiation, an examination of its effects

on tissues in the body compared with its effects on the same tissues explanted in vitro, will indicate to what extent the changes which appear in vivo are due to the direct action of the agent on the individual cells, and to what extent they are caused by vascular damage and other indirect actions

An excellent account of the main applications of tissue culture is given in the new edition of Raymond Parker's *Methods of Tissue Culture*[1] As he points out, there has been a "gradual development of a system of procedures that has been used to advantage in almost every field of experimental biology and medicine, particularly in cytology, histology, embryology, cell physiology, cell pathology, bacteriology and immunology, and in the study of tumours and viruses" His book gives a full and clear account of many old and new tissue culture techniques and their modifications, Joseph P Morgan contributes an interesting review of recent attempts to make a satisfactory synthetic culture medium, there is a chapter on the thorny question of growth measurements and their interpretation, and concluding sections deal with histological and photographic methods An investigator who wished to undertake tissue culture experiments on a modest scale and with limited space and funds at his disposal might well be daunted by the elaborate procedure and equipment described in the earlier part of the book, and it should be remembered that much useful tissue culture work can be done under far simpler conditions But although *Methods of Tissue Culture* is hardly suitable as a handbook for an impecunious beginner, who might find Cameron's *Tissue Culture Technique*[2] more helpful, it contains a store of valuable information that makes it an important reference book in any tissue culture laboratory and a useful guide for more experienced workers who wish to employ some of the special techniques described

Though tissue culture is on the whole more widely used and more highly organised in Canada and the United States than in England, it is being practised in an increasing number of centres here It is used at the Strangeways Research Laboratory for studies in cytology, radiobiology, and developmental physiology, at the Chester Beatty Laboratory, and at the Biochemistry Department of Glasgow University, for investigations into the physiology of growth, at the Radiotherapeutic Department of Cambridge University for analysing the action of antimitotic poisons and radiations, and at the Christie Hospital, Manchester, for radiological research, and at various other centres it is being employed on a smaller scale The latest British institution to make extensive use of tissue culture is the Biophysics Unit of the Medical Research Council at King's College, London, where the method is being applied as one of several approaches to problems of cell structure and growth, utilising various optical techniques of infra-red, phase-contrast, ultraviolet, and electron microscopy In general, cells in tissue culture grow in thin flat sheets, and this property is of value in a more quantitative optical approach to the study of the living cell During the last fifty years many theories of mitosis have been proposed, but even today there are very few measurements of the physical aspects of the process which could be used in developing an adequate theory Tissue culture cells, as A Hughes and others have lately shown, form admirable material for such research

Almost fifty years ago it was discovered that the contents of cell nuclei absorb strongly in the ultraviolet range, and later this characteristic absorption became identified with that of the purine and pyrimidine bases of the nucleic acids It is largely owing to the work of Caspersson and his collaborators in Stockholm that the ultraviolet microscope has became an important tool for the study of individual cells, and his recently published lectures[3] give a good idea of how this work developed and of the ideas it has evoked No better example than this field of research could be chosen to illustrate how important it is that physicists, biologists, and biochemists should learn to understand the advantages and limitations of each other's methods The processes of fixation, for example, involve complex chemical problems as yet too little understood, they certainly lead to loss of material from the tissue By the use of cells in tissue culture, the living animal cell may be perhaps most conveniently studied, and it is possible that the physicist can at least assess and approximately distinguish between absorption, refraction, and scattering There can be no doubt that first class biologists and physicists are needed for research in this field, and that the most fruitful additions to biological knowledge can arise only from collaboration between the two groups The expected precision of thought which the physicist brings to his problems is bound to prove useful here

The Budget

In deciding to charge patients about half the cost of their dentures and spectacles the Government have retreated from the principle that treatment under the National Health Service shall be free of charge, but they have withdrawn only from two salients that were becoming hard to hold For a great many people, better mastication and better vision are of more practical importance than most of the other benefits that medicine can offer, but it has seemed disproportionate that the dental and supplementary ophthalmic services should together absorb £75 million against only £48 million for general practitioner services, and definitely wrong that some 60% of dental expenditure should be on dentures The new arrangements will save some £13 million without, we hope, imposing real hardship With the ceiling of N H S expenditure strictly defined, saving in various other directions will still be necessary in the service, and, with prices rising, all who work in it will have to set their face against every kind of waste if they want to maintain its standards, let alone raise them Against Mr Gaitskell's background of rearmament, devaluation, and shortage of materials, hardly any prospect pleases, but, in the N H S at least, much improvement is still possible within the limits drawn As doctors we can surely be thankful that the Budget, though it makes large provision for defence, does not create an economy in which the aims of peace are forgotten

Annotations

CHILDHOOD OBESITY

Do fat children grow up to be fat adults? There is a general impression, with no figures to support or refute it, that most people who are fat in childhood and early youth become thin later. Nevertheless, the recognised causes of obesity in adults probably operate also in children: they are an inherited (familial) tendency, glandular imbalance, affections of the hypothalamus, injuries to the brain, true overfeeding, and the after-effects of infections. In the U.S.A. there has lately been a reversion to the view that "Fat comes only from food, and obesity results only from eating more than is required to meet the energy requirements of the body".[1] This view has adherents in this country, but Spence[2] and Simpson,[3] among others, doubt whether there is such a simple explanation. In Melbourne Graham[4] puts the blame on "defective personality trends leading to increased intake of food and to decreased expenditure of energy". His treatment is based on an assessment of what the child should weigh for its height and age, followed by dietetic control, physical activities, and comparatively large doses of thyroid. But direct mensuration is sometimes misleading, as Brožek and Keys[5] have shown, the evaluation of leanness and fatness is a complicated problem best tackled by indirect methods. Then muscular exercise, though uplifting, has disappointingly little effect on body-weight. Dodds[6] has calculated that the maximum output of that energy a man can maintain for short periods is about 600 calories an hour. At this rate, a half hour game of squash will roughly balance an intake of two slices of bread and butter or a pint of beer.

There is a common type of fat boy which does not fit easily into any of the categories so far mentioned, and is often classed as "Froehlich's syndrome" or "Froehlich type" because, besides obesity, the children show delayed development of the penis and testicles and feminisation, with prepuberal fat distribution and a gynæcoid pelvis. Simpson[7] analysed some of these cases in detail and coined the term "adipose gynandrism" for them. Even without any specific treatment these children ultimately attain a full normal sexual maturity, though they may or may not lose their obesity. In Bauer's[8] opinion the overweight child is usually also overgrown, and both conditions result from genetic abnormalities (gigantism), though these abnormalities may manifest themselves at widely different times.

Whatever the ætiology of childhood obesity, few pædiatricians in this country would put a fat child under the age of 12 years on a rigorous reducing diet unless there were some exceptional circumstances, and they would be still more chary about prescribing thyroid treatment for such patients.

HISTOPLASMOSIS AND PULMONARY CALCIFICATION

It is nearly 50 years since Darling first saw *Histoplasma capsulatum* in the tissues of patients with a disease resembling visceral leishmaniasis, but it was not until 1934 that the organism was shown to be a typical filamentous fungus. The fungi invade the cells of the reticulo endothelial system, where they appear as round or oval bodies 2–5 μ across, with scattered nuclear material and a refractile edge. They are found in various types of phagocytic cells in the blood and bone-marrow as well as in liver and spleen. Histologically, the lesions have a necrotic centre surrounded by granulomatous tissue. With disseminated infection there is fever, enlargement of the liver and spleen, and anæmia. The disease often simulates tuberculosis, Hodgkin's disease, or carcinoma, and may be associated with them. Most of the cases reported have been in America, particularly in the area bordering the Mississippi valley and its larger tributaries, or in South Africa and Java; only very rarely has it been recognised in the British Isles or elsewhere. Bunnell and Furcolow[1] in 1945 described 10 patients with the disease in Kansas City, and Furcolow[2] now reports on a further 6 from whom *H. capsulatum* was isolated. Of these 6, 2 had laryngeal lesions and 3 had disseminated foci in the lungs visible on radiography. Of these 3, 1 healed with miliary calcification, and another with complete disappearance of the lesions; in the 3rd the condition persisted unchanged for two years, when the patient died of an unrelated illness. Furcolow groups these 16 cases into (*a*) clear uncomplicated clinical cases; (*b*) cases in which the diagnosis was only probable; and (*c*) cases in which the recovery of *H. capsulatum* seems to have been incidental. Of the 16 patients 5 have recovered, and it now seems clear that even overt histoplasmosis is not always fatal as it was once thought to be.

Fresh light was cast on this disorder by the discovery that pulmonary calcification was much commoner among troops recruited from the Middle West than from any other part of the U.S.A. In 1945 Dr. Carroll E. Palmer and his associates began a series of epidemiological investigations with histoplasmin, a skin testing reagent used in much the same way as tuberculin in the Mantoux test. It was found that many tuberculin negative reactors who had pulmonary calcification reacted to histoplasmin. There was also a definite geographical pattern in the prevalence of histoplasmin reactors throughout the country, and a high incidence of lung calcification was found in areas where histoplasmin reactors were numerous. In a survey on over 5000 nurses and freshmen at Ohio State University, Prior and Allen[3] found that 75% of residents from the south-western part of the State gave positive histoplasmin reactions, and that the proportion of positives dropped steadily in those coming from the north and east across the area. Prior et al.,[4] who surveyed 5000 students by means of chest radiographs and tuberculin and histoplasmin tests, also found that pulmonary calcification in Ohio is more closely associated with histoplasmin sensitivity than with tuberculin sensitivity; indeed there was no obvious relation between calcification and positive tuberculin tests. Calcified lung lesions were slightly commoner among male than among female students, and they were also commoner among those from farms than among town dwellers; tuberculin reactors, on the other hand, were commoner among the townsfolk. Although many of the calcified lesions brought to light in these surveys were undoubtedly of tuberculous origin, the findings add weight to the increasing evidence that in Ohio and other Middle western States such calcification is usually the result of a benign form of histoplasmosis. Most of these large scale surveys have necessarily relied on skin tests, which are convenient but are not necessarily the best tool for such work. Possibly infection with an antigenically related organism could give a positive histoplasmin test, but none has yet been found. *H. capsulatum* has been isolated from dogs and rodents, but it is not known whether the organism survives outside the body or how infection is spread to man Until we know more about the epidemiology and pathogenesis of histoplasmosis we can only repeat [5] that the association of pulmonary calcification with histoplasmin sensitivity in certain well defined areas is suggestive, but not conclusive, evidence of a causal relationship

SURGERY AND PREVENTIVE MEDICINE

Francis Bacon, that reviver of the experimental method, proposed eight qualities for the scientist They were desire to seek, patience to doubt, fondness to meditate, slowness to assert, readiness to reconsider, carefulness to dispose and set in order, neither affection for what is new nor admiration for what is old, and hatred of every kind of imposture Sir James Learmonth, reviewing, in his Heath Clark lectures of 1949,[6] the contribution of surgery to preventive medicine, likens these precepts to a protracted drip transfusion into British medicine, which did not produce its maximum effect until it distended the veins of John Hunter Considering them in turn, he remarks how variously desire to seek reveals itself, appearing both in those who patiently collect data relevant to an immediate need, and those who, like Charles Darwin, speculate on the data they have collected, so achieving a new synthesis, or are arrested by an exception where another man might be intent upon a rule Patience to doubt, "all too easily taught to recruits in science," brings its own risks, for it is easier to stand back and wait for certainty than to use constructively what is already known In dealing with people, a half plan is sometimes better than no plan When Jenner and Lister made their great contributions, one to preventive medicine, the other to surgery, the science of bacteriology was still unknown They acted resolutely, in a half light

Fondness to meditate is nowadays almost denied the scientist, pressure of work constantly hounds the teachers, and students are not even being prepared for the discipline of meditation Sir James suggests that at some stage in school education simple rules might be introduced by example, and inculcated by practice, to help the student to meditate to some purpose In examinations, he finds, the mark of the candidate who is a stranger to meditation is the phrase "according to X" he only has courage in the opinions of others, and as Arnold Bennett put it "sprinkles a thin powder of dullness over everything" The best method of selecting the worth while men from recruits, Sir James thinks, would be "to propound a presently insoluble problem in the morning and to collect the papers in the evening" Candidates would be free to meditate, and to meet and talk with each other, and with other groups, so that they would receive the stimuli of other minds

Slowness to assert, he says, is a harder precept for surgeons to follow than for those engaged in preventive medicine, fortunately it is always possible to recant a mistaken opinion, and readiness to reconsider ensures that this step can be taken without shame The easiest of the precepts to inculcate should be carefulness to dispose and set in order, and most students nowadays appreciate its purposes at least Recorded observations, they know, often point the way to discovery, as they did for Darwin Order, moreover, includes clear thinking, the forerunner of judgment, and we appraise our great men by their judgment By the use of this very quality the scientist strikes a balance between the new and the old in medicine, and learns to recognise and repulse imposture

Grounded in these precepts, surgery and preventive medicine have supported one another in many ways and Sir James Learmonth foresees future opportunities for collaboration While methods of preventing disease are still being sought the surgeon can offer many temporary expedients Thus he may be able to find methods of access to parts of the body where pathological processes have still to be studied and measured, and he can often eradicate disease in its early stages, prevent the development of some deformities, help to counteract local morbid processes, and suggest indirect ways (e g, by division of sympathetic nerves, or the administration of endocrine preparations) of breaking some link in the chain of pathological processes which cause disease In short, as Sir James said, quoting G M Young, he can help "to conserve and preserve the young and active, so that they can put their strength and vigour at the service of the community, and to preserve the old so that they can put their experience to similar use" But when his colleagues in preventive medicine find ways to break an earlier link in any of the chains, then like a good follower of John Hunter the surgeon will stand back, and cease to operate for a condition which he cannot directly cure

WHY MOSQUITOES BITE

APART altogether from the conditions that bring mosquitoes out in force—darkness and night time, low lying ground, a hot steamy atmosphere, and so on—people living in mosquito infested places seem to show individual differences in their liability to bites The same sort of differences are said to exist elsewhere and in regard to other insects—even our own humble midge In Canada, where most of the country is infested with aedes mosquitoes, Brown [1] and other zoologists at the University of Western Ontario, having spent two years studying the relative attraction of animals for mosquitoes, have lately turned their attention to man—or rather, dummy men—as a subject for study in Ontario and in central Labrador

Their technique is ingenious but simple Two stainless-steel tanks, each holding 100 lb of water kept at any desired temperature by electric heaters, represented the human torso For some experiments heads were attached The dummies, dressed in shirts and jerkins of various colours and materials, were set up in a forest glade The number of mosquitoes landing on a dummy in 1 or 2 minutes was then taken as the measure of its attractiveness in the prevailing external conditions of temperature and humidity At air temperatures over 60°F a dummy with moist clothing was found to attract 2–4 times as many mosquitoes as a dry one, but at lower temperatures, and particularly when humidity was high, the dry dummy was the more popular, even though its surface was 1–3°F cooler than the moist one's At air temperatures of 57–74°F, the dummy containing water at blood heat attracted three times as many mosquitoes as one filled with cool water, making its surface 14–24°F colder Clothing both dummies in a felt shirt, which reduced the difference in their surface temperature to 4°F, made them equally attractive, whereas when both dummies were moistened the warm one became twice as attractive as the cool Clothing soaked in water saturated with carbon dioxide was no more attractive than normal wet clothing, but a clean jerkin became twice as attractive when two men rubbed themselves down with it after sweating heavily By affixing a head and passing 10% carbon dioxide out through the dummy's mouth at 2 litres per minute, the attraction of the head and body were raised to half as much again, whereas the apparent exhalation of pure carbon dioxide doubled the attraction of the body and tripled the head's Breathing out ether or petrol vapour also increased a dummy's attraction, ordinary air had no effect, and chloroform vapour repelled the mosquitoes

[1] Brown A W A *Nature Lond* 1951 167 202

Turning to colour and texture of clothing, white clothing was not so attractive as black, and either light red or light blue was less attractive than dark shades, light blue was more attractive than pink The mosquitoes liked settling on broadcloths or crepes but not on satin, and certainly not on luminescent satin Finally—and this may well start a new fashion in tropical kit—there was general agreement among the mosquitoes that the traditional cotton shirt and drill trousers made a far better landing ground than woven 'Nylon' Unfortunately, however, nylon fabrics do not absorb perspiration freely as do cotton or wool,[2] and this may make them uncomfortable for next to skin wear in hot climates

THE HEALTH OF WELSH STUDENTS

YOUNG people often reach our universities in haphazard ways Academic ability is not the only quality driving them they may be ambitious, or have ambitious parents, they may wish to share the company of friends, they may enter, and even choose a particular course, in an attempt to solve their personal problems Perhaps only a small proportion are taking an inevitable and fully appropriate step Nevertheless most of them gain from a university training, and many could probably gain more if they were on top of their mental and physical form Recent surveys [3] suggest that this is seldom the case, but it seems, from a pilot survey at Cardiff [4] made in the Lent term, 1950, that students do not suffer more sickness than an equivalent age-group in the general population The survey was conducted by post, and some of the figures for sickness are believed to be artificially low The comparison with non students of the same age, however, was made in terms of the "health index"—that is, the proportion who reported no complaint during the period of the survey Just over half the men, and nearly 46% of the women students, reported such a clean bill of health, for the general population aged 16–24 the comparable figures were roughly 46% and 35% There was slightly more sickness among the women students than among the men, but chronic or continued illness accounted for rather more of the total sickness in men than in women The types of illness were much the same in the two groups, except that men were much more liable than women to chronic nasal catarrh, ear, nose, and throat conditions and skin conditions

The facilities offered by the University for the diagnosis of tuberculosis are good Mass miniature radiography was offered to all students in 1949 only 2 students with active pulmonary tuberculosis were found among 3178 examined, and 5 more were kept under observation There were 20 healed lesions Clinical students at the School of Medicine are offered full size chest X rays at six monthly intervals and among these there were 2 cases of active disease in the period reviewed All medical students are Mantoux tested, and negative reactors are offered B C G vaccination.

General medical and surgical conditions accounted for over a fifth of the chronic illness in both sexes, but by far the heaviest toll was taken by psychological illness, which was responsible for just on half the chronic illness in both groups In the Cardiff survey, 13% of students had major psychological difficulties, and another 20% had minor difficulties, in the five colleges of the university as a whole 37 students in all academic years failed to complete the 1949–50 session through mental ill health Psychoses were rare, and the common disorders were anxiety states, obsessional neuroses, psychosomatic symptoms, and hysterical manifestations Dr R A N Hitchens, Dr G Grant, and Dr E McKnight, who present the report, attribute these disorders to the facts that many students were away from home for the first time, most were in the late stages of adolescence, when emotional instability is common, some had been damped by previous academic or social failure, and others coupled anxiety over their studies with a poor insight into their own ability, unhappy home relationships, including parental discord, affected others, and in some psychological troubles were reinforced by financial anxiety Sexual ignorance and frustration seemed to be at the root of many difficulties, and was relieved by frank discussion, and the report insists on the value of explanation and reassurance in tiding students over emotional crises of any kind A background of general health education was lacking in nearly all the men and three quarters of the women, and this gap should be filled, the writers of the report suggest, before the students leave the university Breakdowns could also doubtless be reduced by appropriate selection procedures, but it is worth remembering that such procedures, if successful, would only keep those liable to breakdown out of the university they would not do away with them altogether It is time we knew a great deal more about adolescent instability—the forms it takes, the outcome to be expected, and what we ought to do about it—whether it crops up in the university, the home, or the juvenile court

AUREOMYCIN INTRAMUSCULARLY

WHEN given by mouth, the usual route, 'Aureomycin' may cause nausea, vomiting, and diarrhœa and irritate the mucous membranes of the mouth and anus Intravenous injection occasionally led to thrombophlebitis in the past,[1] though this risk is said to be eliminated in the present purer products, and intramuscular injections have been too painful for routine use owing to the low pH of the solutions There is an advantage in having a solution which can be injected intramuscularly or subcutaneously, for cases where a rapid effect is needed or swallowing is difficult Seyberlich [2] in France has devised the following preparation which he claims not to be irritating when injected into a muscle He dissolves 2 5 g of aureomycin in 5 ml of olive oil which has previously been washed with alcohol and sterilised He then adds this solution to 10 ml of procaine penicillin in sesame oil with aluminium monostearate Before injection the preparation is warmed and shaken well He explains that the vehicle delays absorption and prolongs the action of the aureomycin, so the dosage can be reduced without loss of effect, his routine is one intramuscular dose every twelve hours Seyberlich has given 300 injections to patients of all ages, and he reports no local reactions, and no complaints of pain He mentions, though without detailed evidence, that the results obtained with his preparation are as good or better than with the usual tablets by mouth He clearly should have included in his paper some blood aureomycin levels after intramuscular doses of this oily preparation Unfortunately, Seyberlich's experience does not conform with that of Whitlock and his co workers [3] in Philadelphia, who used a buffered aureomycin plus 1% procaine and found that injections still caused intense local pain and induration, with febrile reactions This disparity might be worth investigating

---

MR A. S BLUNDELL BANKART, consulting orthopædic surgeon to the Middlesex Hospital and consulting surgeon to the Royal National Orthopædic Hospital, died in London on April 8 at the age of 71 or otherwise more expensive ward he can claim from the government the cost of ordinary ward treatment to set against his expenses The scheme is very new and has not yet had time to settle down The Saskatchewan scheme has been going a little longer, since 1947, and again provides ordinary ward treatment It has, however, had two developments of interest in England One is that in order to reduce what appeared to be an excessive demand for medicines a deterrent fee of 20% was put on all prescriptions—i e, the province only paid 80% instead of 100% of the cost of prescriptions The result was that the number of prescriptions ordered dropped by 22% In the south west corner of the province a start has been made in providing a general practitioner service so that the health service is complete This is a very recent development and it is too early to say how the scheme will progress

Methods of Avoiding the Cost of Inpatient Treatment

The foregoing schemes are all based on accepting the high rate of cost and spreading the payment by insurance Another line of approach has been an endeavour to reduce the demand for inpatient treatment This has been attempted by (*a*) better diagnosis outside the hospital so that admissions for investigations can be cut down, (*b*) the encouragement of early ambulation, (*c*) convalescent care and rehabilitation, and (*d*) treating the patient in his home

IMPROVED DIAGNOSIS

The whole science of diagnosis, particularly in the large private clinics, has been streamlined into a regular business process In the clinics a wide variety of tests are done as a routine, so that the specialist concerned has the results ready to hand when the patient first comes to see him At one large clinic, for instance, the medical staff of 160 see 600 patients a day, every one of whom is fully investigated Extending from this clinic there are various other methods of getting the patient investigated outside the hospital, so that the diagnosis can be made before he reaches hospital and, indeed, partly in the hope that he will be found not to need inpatient investigation or treatment at all

The Pratt Diagnostic Hospital at Boston is perhaps the most developed voluntary method of providing expert diagnosis before deciding whether the patient should be admitted to an acute hospital In this case the patient is admitted to a purely diagnostic hospital, and will subsequently be transferred to an acute hospital or sent home, as the results of the diagnosis indicate

Another process which should be mentioned at this point is that of group practice This varies from the simple doctor's office, where there may be two doctors who between them can afford to have simple equipment for making clinical tests, to the much more elaborate groups run under the ægis of the Hospital Insurance Plan, where some fifty doctors work as a group, half of them being general practitioners and half specialists In this case the general practitioner is able to get all the specialist opinions he may need within his group before sending the patient to hospital This presumably obviates the need to send a patient to hospital with such a diagnosis as ? abdomen, leaving him to occupy a bed while the diagnosis is made

All these are devices which by improving the possibilities of diagnosis, are in fact a welcome relief to hospitals even if that is not their primary object

EARLY AMBULATION

The practice of early ambulation is spreading and the patient is now commonly expected to get out of bed the day after the operation and to go home in a very short time We were given the following as a guide to the time required, after operation, before discharge of a patient appendicectomy 3–4 days, gastrectomy 12 days, abdominoperineal resection of rectum 16 days On the same principle we were told of mothers and babies being sent home on the 6th day The coincidence that a new medical procedure is both financially just what is wanted and also good for the patient is so striking that we felt bound to ask whether, finance apart, the procedure is the best possible for the patient The doctors all agreed that it was, provided the time of discharge was not too rigidly adhered to and could be varied according to the patient's home conditions, general health, and so on Almoners and convalescent superintendents, who know more of the patient as a person, agreed that it was bad for the patient to be left in bed too long, but pointed out that it was possible to get him up too soon Be that as it may, the practice is very widely adopted and eliminates the need for convalescent homes for short term cases On one occasion when we inquired what happened if a patient's home was unsuitable we were told that he was kept in hospital for a little longer

CONVALESCENT CARE

Convalescent homes as a whole appear to be in much the same state in the U S A as they are in England. There is a committee of the United Hospital Fund for New York which is trying to raise standards by arranging meetings of matrons and trustees of convalescent homes, much as the Convalescent Homes Committee has done in Thanet and Brighton The tendency is for the more progressive homes to take patients at an earlier stage of recovery, and since more money is available in America they have been able to adapt themselves more readily than in England

Without going into details of our inquiry, it is sufficient to say that the progressive homes take a much higher percentage of bed cases, and pay a great deal more attention to physiotherapy and dietetics Patients discharged early from hospital on the principle of early ambulation are sent home and not given convalescence Since a short period of convalescence is just what they might be supposed to need, this is curious We could only suppose it was due to a lack of knowledge of the advantages of convalescence, or to financial reasons In practice there is a tendency for homes to get mainly long term cases, noticeably cardiacs and chronics. We were rather surprised to find that more use was not made of these homes, for the saving in the cost of maintenance is very large, hospital costs being in the order of three to four times as much as convalescent homes

In the Master Plan for New York, which is the official building plan approved by the Surgeon General's department for grants under the Hill Burton Act, it is proposed that convalescent homes should actually form part of the hospital building This is an intriguing thought, but as yet it is only an idea on paper In this plan it is suggested that convalescent beds should be provided in the proportion of 25% of the general beds

REHABILITATION

It is generally admitted that England has been leading in rehabilitation, owing to the great strides made by the Royal Air Force during the war However, much thought is being given to rehabilitation in Canada and the U S A In particular we saw institutions for veterans (ex Servicemen) in Toronto and Montreal where the re establishment of men injured in industry was carried to great lengths At the Workmen's Compensation Board Center at Malton, Toronto, they take the view that re establishment to the point that a man can return to light work is no use He must be fit to return to his own work, however arduous, or must be retrained altogether To ensure that a man can return to his own work, the actual implements and materials of his trade are available at the centre and a lumberjack only returns to work after he has been able to hew and handle lumber in the centre The same applies to railway gangers, dockers, labourers, and so on Much imagination had been shown in providing both the appropriate work and the incentive to do it so that the speed of recovery was maintained It was interesting to notice that this particular institution, which is doing outstanding work, is housed in an ex R.C.A.F camp with no expensive equipment or furnishings And such of the equipment as is not provided by employers is made by the patients themselves

In New York perhaps the most outstanding case is the Altro Workshops where people recovering from tuberculosis and compensated heart disease are given work, according to a time schedule laid down by their doctor They are paid regular rates and the goods are sold on the open market Anyone who has completed his rehabilitation is discharged, but the principle of sale on the open market is maintained in order to make clear to the patients what they will have to do on return to normal life.

HOME CARE

Interesting experiments are being made by the Montefiore Hospital in New York in extending hospital care to poor patients in their own homes These arise from the shortage of beds for long term patients for which the conventional remedy is new buildings This would involve a heavy cost, and to avoid it these hospitals have hit on the ingenious device of using the patient's bed instead of providing one in the hospital The patient gets the advantage of staying at home and the hospital is saved the cost of building

The scheme is intended to provide patients in their own homes with everything they would receive as a hospital inpatient They are visited by hospital doctors, by district nurses, who aim at training the patient and relatives in all necessary nursing measures, by medico-social service workers (almoners) and, if necessary, by physiotherapists or psychologists The services of a visiting dietitian are available, and, if patients cannot afford the diet prescribed, the necessary food is provided If no one is available to buy or cook food, a housekeeper service is provided, generally by a suitable neighbour If a consultant is necessary, transport to the hospital outpatient department is arranged

Any necessary furniture, drugs, dressings, or appliances are provided—even a hospital bed if the patient's own is unsuitable Minor operations are performed in the home

The service is chiefly suitable for long term cases, for clearly its money saving features come into full play when the patient is set up with the necessary equipment, and a routine is started that can largely be maintained by the patient or his friends The service can, however, be used for simple short term cases, thus leaving beds free for more serious ones The hospital maintains that this method saves money to the hospital Whether it saves the time of the staff was more difficult to determine, but we were told that there should be a saving in nursing staff, since the nurses are sent out to teach the patient's relatives how to look after him rather than to do the nursing themselves

This scheme has great possibilities, but in New York it is heavily restricted by the need to apply it only to patients who are either indigent or what is termed medically indigent "—i e, unable to pay their doctor As, however, the patient must also have good enough accommodation to enable him to be properly looked after, and these conditions tend to be mutually destructive the scheme can only be applied on a small scale As the financial requirements do not now apply in England it seems that schemes of this type may well achieve success here

ACCOMMODATION FOR MEDICAL STAFF IN HOSPITALS

J W D GOODALL

M.D, F.R C P.E

MEMBER OF TEAM INVESTIGATING FUNCTIONS AND DESIGN OF HOSPITALS (NUFFIELD PROVINCIAL HOSPITALS TRUST AND THE UNIVERSITY OF BRISTOL)

WHAT accommodation is needed in hospitals for the use of the medical staff, and where should it be placed? My comments to these questions are based first on my own observations and secondly on specific details of the accommodation at present provided in 22 hospitals (10 teaching and 12 non teaching) 4 of which are among the most recently built in the United Kingdom

Present Position

Sleeping accommodation—There is a striking similarity in the sleeping quarters in these 22 hospitals Nearly all of them provide a bedroom or bed sitting room for each resident doctor, either in a separate block or in flats in the main building Baths, lavatories, and sometimes a common sitting room are provided nearby A notable exception is in Glasgow, where in the 2 hospitals studied the residents sleep in quarters attached to their wards This is considered highly satisfactory by both the doctors and the administrative staff, on the grounds that it enables the resident to give maximum attention to the patients Women residents are as a rule accommodated in the same way as their male colleagues In a very few instances they sleep in the nurses' home, but the only usual concession to them is a separate sitting room and bathroom In maternity hospitals a bedroom near the labour-ward is sometimes provided for the doctor on duty

Dining rooms—Commonly there is a residents' mess situated either near the sleeping quarters or centrally in the administrative block, and consisting of a dining room, sometimes with a sitting room attached It is usual for the mess to have a separate domestic establishment and for the senior visiting staff to have meals there when they want them As an alternative, some hospitals have a central cafeteria or dining room open to all members of the hospital staff and visitors This is not always popular, and, in one hospital where this system was instituted, first the senior nurses and then the doctors requested to have separate dining-rooms

Recreation—Only 10 of the hospitals possess a medical library, and even fewer have a " quiet room " for reading A radio, billiards, and tennis courts are often available, the last usually being shared with the nurses At Great Ormond Street sun bathing was the only recreational activity recorded, apart from the use of a medical library The Rotunda Hospital in Dublin is very gay, with tennis, squash, croquet, billiards, table tennis, and dancing

On the ward—The accommodation for doctors in the wards varies A doctors' room is provided in almost all teaching hospitals, but rarely in non teaching hospitals, and the teaching hospitals generally provide a lavatory for the doctors, while the non teaching hospitals do not Laboratories or clinical side rooms are found in most of the teaching hospitals and in a few of the others Demonstration rooms, where patients can be shown to students or where clinical meetings can be held, are sometimes provided in the teaching hospitals A room for waiting relatives, or relatives of patients requiring an interview with the doctor or sister, is rarely found Great Ormond Street is exceptional in having a combined waiting and interviewing room attached to each ward Of the 22 hospitals 9 have what they call treatment rooms, though not in every ward Among the wards mentioned as having treatment rooms are surgical, gynæcological, mental, and children's wards In Great Ormond Street there is a treatment room to each 10 bed unit happens to be at the time In Bath United Hospital the need for a room in which relatives can be interviewed and in which on occasions a relative may spend the night has been so strongly felt that side-wards have been used for this purpose It has often been suggested that interviews could take place in the doctors' room, but there is no guarantee that this room would be unoccupied when needed Privacy is essential, and experience shows that a separate room with a neighbouring waiting room is desirable The normal 25–30 bed ward produces enough relatives to justify a small interviewing room and waiting room, but these might prove adequate for a unit containing as many as 60 patients

Treatment Room

Only a minority of hospitals have treatment rooms, and these use them in rather different ways At the Royal Victoria Hospital, Newcastle, there has been a treatment room for the past 3 years to which patients are wheeled on a stretcher to have their dressings changed Beds are not wheeled into it and it is not a specially sterile room In one surgical ward in Bristol a treatment room is to be constructed as a ward annexe to which most patients will walk for dressings The Radcliffe Infirmary at Oxford has well equipped treatment rooms which are comparatively new

A treatment room concentrates much of the work of the ward into one "workshop," offers privacy, and removes to a large extent the need for screens Dressing trolleys need no longer be taken round the ward from patient to patient A sterile atmosphere may be provided by air conditioning and the patient is remote from the contaminated dust of the ward Moreover, patients can no longer see the sufferings of their neighbours through cracks in the screens—a sight which is often upsetting

Sir James Spence (1947) visualises a treatment room in each unit, where "all dressings, lumbar punctures and other painful manipulations can be carried out, and where anæsthesia will be frequently used" Bourdillon and Colebrook (1946) point out that "the practice of dressing wounds in a special room designed for that purpose should have considerable advantages, but unless special precautions are taken it must involve the danger of exposing each successive wound to a cloud of organisms disseminated from the dressings of the previous patients" In some hospitals, as for example in Sir James Learmonth's wards in the Royal Infirmary, Edinburgh, patients are taken into the nearby surgical theatre for dressings This is convenient only if the theatre is close to the ward

It is clear that opinions vary as to the purpose and equipment of a treatment room The demand has come principally from surgeons for the dressing of wounds, and perhaps the best example of how this demand has been met can be seen in the burns unit of the Birmingham Accident Hospital

Although less is heard of the physician's need for a treatment room, this undoubtedly exists Medical wards contain many patients whose special treatments are better carried out in a treatment room than in the ward behind screens For example, lumbar puncture, chest aspiration, blood transfusion, sternal puncture, and catheterisation are among the many procedures more suitably carried out in a treatment room There may be a conflict between the conception of a treatment room as a place akin to a small operating theatre with great emphasis on sterility, and the rather different conception of it as a place where most treatments, whether by doctors or nurses, can be done In practice, a treatment room may be used for either purpose The surgeon may treat his wounds or burns, or dress his plastic cases in this room, excluding infected patients if he wishes Since most of his patients will be "clean" this will suit his purpose well The physician, pædiatrician, or gynæcologist may equally well use the same type of room attached to their own wards, for other kinds of cases.

Attention must always be paid to the prevention of cross infection, since concentrated risk may make a treatment room unusable Special ventilation is expensive but necessary in rooms used for the dressing of burns, wounds, and plastic work, and it would be unreasonable to accept a lower standard of antisepsis for other cases One treatment room per ward of 30 patients may be expected to meet the requirements of general medicine because there will be few dressings, and fewer treatments needing the use of a treatment room, its main use would be for diagnostic tests But in surgical wards and in wards admitting special types of patient more than one treatment room may be required

OUTPATIENT DEPARTMENTS

Whether consultations with outpatients should take place in the vicinity of the wards or in a separate outpatient department is still undecided In either case suitable rooms will be needed Fortunately the requirements of different specialists do not, in general, affect the rooms but only their equipment

A consultant needs a room where he may interview patients in privacy, an examination room with a bed or couch, and three dressing rooms (so that one patient can be examined, while the next is undressing and the third is dressing) It is an advantage, particularly in dealing with gynæcological patients or those with cancer, to be able to screen off a part of the consulting room to accommodate a secretary This room should have a wash basin and lavatory nearby

Minor treatments, such as injections, can often be given conveniently in the consulting room, which should be fitted with a steriliser and instrument cabinet Where many tests and treatments are likely to be done it is better to have an additional room for this purpose and in which urines can be tested or specimens taken for laboratory purposes

In the interests of economy different consultants will probably use the same suite of rooms at different times Since more whole time consultants are likely to be appointed it is worth considering whether each team under a whole-time consultant should not be provided with a suite of rooms for their exclusive use

CONTROL OF MEDICAL MAN-POWER

Statement by Central Medical War Committee

MANY doctors, and in particular those who have reserve commitments to the Armed Forces, have expressed anxiety about their position and possible liability for active service in the event of war For a long time the Central Medical War Committee has been urging the Government to set up suitable machinery for the provision of advice as to the availability for recall in an emergency of individual doctors with reserve commitments The committee is now authorised by the Ministries concerned to publish the information given below

It will be remembered that during the last war the allocation of medical man power between the various Services was arranged on the advice of a professional committee, the Medical Priority Committee, while the actual recruitment of doctors into the Services was undertaken by other professional committees—the Central

Medical War Committee, the Scottish Central Medical War Committee, and the Committee of Reference, with the advice and assistance of local medical war committees The Medical Priority Committee, the Central Medical War Committee, and the Committee of Reference have continued, since the end of the war, to organise the recruitment of doctors with national service obligations

Discussions have now been proceeding for some time between the representative medical organisations and the Ministries on the establishment of new machinery of control designed to take account of the changes in the structure of the health services brought about by the National Health Service Acts Under these new arrangements, the control machinery will be broadly similar to that now existing, new area committees will be established to deal with the various branches of the medical service—i.e., the general practitioner service, the hospital service, and the public-health medical service It is hoped that the new machinery will be fully established within the next two or three months

In the meantime it has become necessary for the Service Departments to begin reviewing the position of doctors with reserve commitments, and to earmark those who would be the first to be recalled to the colours in the early stages of any future war This procedure is part of a wider review which covers reservists in all walks of life, and is not confined to doctors Arrangements have been made for the doctors concerned to be "screened", that is to say, for their commitments in civil life to be reviewed so that if the recall of a particular doctor in the early stages of a war appeared likely to prejudice some important branch of the civilian medical service, cancellation or deferment of recall could be considered

It has now been decided, after consultation with the Central Medical War Committee and the General Medical Services Committee, that the Central Medical War Committee shall undertake the interim "screening" of reservists who are general practitioners, and that the local medical committees, established in accordance with section 32 of the National Health Service Act, 1946, should be invited to assist the Central Medical War Committee in this work, a lay member nominated by the executive council being coopted to the local medical committee for this purpose In Scotland similar arrangements are being made for the "screening" to be carried out by the Scottish Central Medical War Committee with the cooperation of the local medical committees

Purely as a stop gap measure, provisional "screening" of doctors in other branches of the medical profession has already been carried out by medical officers of the Health Departments This "screening" will be reviewed by the appropriate professional committees as soon as agreed machinery for local consultation has been set up

The 'screening" procedure described above is concerned solely with the question of the effect of recall on the civilian medical services It is not concerned at all with any question of personal hardship, which, in the case of a reservist, whether a medical man or layman, is a matter for the consideration of the Service Departments, to which appeals may be made at the time of recall.

Before Our Time

FRANCISCO DE LA REYNA AND THE CIRCULATION OF THE BLOOD

J J KEEVIL
D S O M.A., M.D Camb, F S.A

L M. PAYNE
F.L.A.

FROM time to time in medicine a brilliant guess is made, holds the field for a while, and is forgotten, only to be revived later and established on a basis of scientific evidence An example is to be found in Francisco de la Reyna's book, published in Spain about 1546, where he asserts, a century before Harvey, that the blood circulates In Spanish this work is generally known in brief as *Libro de Albeyteria*, but its full title may be rendered in English as follows

> The Book of the Craft of the Horse leech in which may be seen all illnesses and accidents whatsoever that may befall all manner of animals and their cure Similarly there will be found the colours and features by which a good horse can be recognised, as well as a good mule The most extensive that has so far been seen. Expounded by Francisco de la Reyna farrier resident at Zamora.

This work must have been extremely popular among Spanish veterinary surgeons, who could find in it an accurate account of the signs and symptoms of innumerable equine diseases, and of methods of treatment which were in general simple and practical, set out with considerable charm of style As a result of these qualities it passed through many editions, but its very popularity has been the cause of its great rarity today Copies were so much used while actually carrying out treatment that they became damaged or worn out

THE ACCOUNT OF THE CIRCULATION

Reyna divides his book into two parts, the first, which deals with the work of a horse leech is written wholly by himself, the second, which is concerned with the craft of the farrier, is an enlarged and amended version of the work of Juan de Linuesa He sets out his views on the circulation of the blood without any particular emphasis, and some of the techniques he advised show that he took it for granted. Thus his technique in phlebotomy differs little from that practised today He dissected down to the vein with a lancet, lifted it up, and with needle and thread passed two ligatures round it After bleeding he tied the *lower* ligature and then the *upper* This order in itself indicates that he did not think that the movement of the blood was a simple pendulum one Similarly in treating bleeding from the palate he stresses the need to keep the head high

Towards the end of the book he writes in the form of question and answer, addressing himself to apprentices and beginning each section "If they should ask you ", and it is in this part of the book that the following passage occurs

> "If they should ask you why, when they bleed a horse from the fore legs, or from the hind legs the blood comes from the lower part and not from the higher The answer? In order that you may understand this matter you must know that the main veins emerge from the liver, and from the arteries of the heart, and these principal veins are distributed throughout the limbs in this fashion—in branches and thin membranous vessels through the external parts of the fore legs and hind legs And from there all these membranous vessels turn round to flow through the main veins which ascend from the hoofs through the fore limbs to the interior in such a way that the veins of the exterior have as their function to convey the blood down, and the internal veins have as their function to carry the blood upward in such a way that *the blood travels in a circle* [*torno*] and as a wheel, through all the limbs and veins, it has the function of carrying nourishment to the inner parts right up to the emperor of the body which is the heart which all the parts obey and that is the reason [for bleeding coming from the distal end of a deep vein]'

Without in any way anticipating the discovery of the capillary circulation, Reyna appears to recognise the existence of the gap in the closed circulatory system which that discovery was to fill

> 'Before the blood can enrich itself he writes, 'it must first alter into the four humidities first it changes in order that it may pass from the little veins to infuse itself throughout the limbs and the porous tissues

secondly it changes while it is thus diffused so that it can moisten these tissues Thirdly it changes while it is there so that it may repair and support any wasted parts It travels on and again separates the humours. Fourthly it changes since in any given place it soaks into the limb and takes on its character, that is in order that it may recover and restore, what gave it its heat, and use up the air, and repair the changes caused by a cruel world [i e, by wear and tear] "

TEACHING OF THE TIME

Reyna's anatomical views are highly traditional in most respects, the great exception being those on the circulation of the blood This is the more surprising by comparison with his teaching that the brain is a chimney for the smoke from the heart, expelling it through the eyes, nose, and mouth He describes digestion as taking place in four stages in the mouth, stomach, liver, and tissues, that in the stomach separates waste from nutriment, the latter (chyle) is carried to the liver, where it is coloured and is then distributed to the body according to its needs Blood is formed from the most "temperate" part of the chyle, the other humours from other appropriate portions If any chyle is formed in excess, it must be purged by the bowel, or by bleeding, or by dieting, or by other similar methods of depletion Purgation by the bowel should be regulated as a result of studying the blood removed at bleeding There are two kinds of blood the arterial or vital, and the venous or nutritive The arterial flows from the heart, the venous from the liver The seat of the spirit is the heart, it is vaporous, controlling movement, sensation, and warmth, and it is this spirit which is manifested in all the pulses

His pathological theories were the current humoral ones, he stressed the importance of a knowledge of anatomy in order that the humours responsible for any illness might be easily identified and abnormalities recognised Diseases being seasonal, a knowledge of the qualities of the humours and the seasons was required in order to appreciate the relationship But although the seasons were a factor he attached more importance to any form of excess, whether in eating, drinking, exercise, rest, or exposure to heat and cold The four qualities of heat, cold, wetness, and dryness, and their combinations are discussed in relation to the four humours Health consists of the right balance between qualities and between these and the corresponding humours—e g, heat and wetness, and the blood This concept is related to the four seasons, thus blood is dominant in March, April, and May which were, perhaps arbitrarily, classified as hot and wet—at least in Spain But the actual local quality of the weather at any season does not appear to have affected this seasonal classification

He compares the art of curing illness to the work of a gardener, who, finding an irrigation channel blocked, removes the obstruction and allows the water to flow to the plants He thus appears to subordinate the healer to the *vis medicatrix naturæ*, but in practice he does in fact advise a less passive rôle, this was inevitable in view of the long held and still prevailing view on the treatment of all diseases by the exhibition of their opposites

He was not wholly free from the influence of astrology (horses' tails should not be docked at certain seasons of the moon), or from alchemy (powder of lizards was of value, and so was an ointment made from certain black worms which emerged from the earth in May, June, July, and August, "as long as a finger," and had to be fried in oil), but in general he used such simple dairy produce as eggs and butter for dieting and for surface applications, and such vegetables and grain as would be found on any farm Qualities associating these products with the humours and the seasons indicated their appropriateness for any condition, thus butter is cold and wet, honey is hot and dry, yolk of egg is hot and wet Since all treatment was by opposites the horse-leech had an easy guide to prescribing, he need only remember that hot diseases must have cool medicaments Plethora must be treated by bleeding

Thus, between much that is now known to be error, Reyna believed that the blood circulated, that in the course of that circulation it was diffused in the tissues, that it was associated with the warmth of the body, and that it gave off air Spain has never claimed for Reyna the discovery of the course that the blood followed and it need hardly be stated that no such claim is made for him here Prof H E Sigerist has inveighed with much eloquence against the present tendency, particularly in the English speaking world, to attribute paternity to every advance in medicine, every new discovery If such a protest needs any support, it is surely to be found in such books as the *Libro de Albeyteria* Reyna should be recognised as giving expression to a belief which, if not clearly defined, was evidently fairly widely held in 1546, since his book led to no protest

EDITIONS OF THE BOOK

The book was certainly first printed about 1546, the copyright—which was granted by Pedro de Lovos on behalf of the King of Castile—being dated at Madrid, Nov 21, 1546 The title, *Libro de Albeyteria*, was used again in 1550 by Lopez de Zamora, suggesting that Reyna's book had achieved a success during the previous five years, which Lopez was quick to exploit

Although many editions have been recorded by Palau in his *Manual del Librero Hispano Americano*, there is one edition which has not previously been identified this is the edition of 1556 Palau cites the following editions 1546, 1552, Mondoñedo, 1553, Zaragosa (doubtful), 1564, Burgos, 1580, Salamanca, 1582, Alcala, 1583, Alcala, 1603, Alcala (first annotated edition), 1617, Madrid, 1623, Alcala, 1647, Alcala The annotated editions of his work were probably published after his death There are copies of 1603 and 1623 editions in the British Museum The notes are by Ferdinand Calvo, and although he doubtless improved the purely veterinary part of the book, he seems to have regarded Reyna's description of the circulation of the blood as irrelevant He omitted the sentence about the heart being "the emperor of the body" from the 1603 edition and suppressed the whole description from subsequent editions

A copy of the first edition is in New York, in the possession of the Hispanic Society of America, and is stated to have been printed at Burgos Two copies of the Mondoñedo edition have survived, one at the Hispanic Society, the other in the National Library, Madrid, and the British Museum has a copy of the 1580 edition in which the colophon is incorrectly dated 1570 No copy of the doubtful 1553 Zaragosa edition is known In the library of the Royal College of Physicians there is a copy of the edition of 1556, which has never been recorded, and of which this is therefore likely to prove the only surviving copy It is a revised edition, priced at two maravedis a copy Certain pages are missing, but were made up in manuscript in the late eighteenth century, or a little earlier The copyist states that he had before him a Zaragosa edition printed by the Casa de Lorenzo y Diego de Robles hermanos in 1583, and that he considers the 1623 Alcala edition superior to this 1583 edition, but wishes to use the earliest one available to him

The 1556 edition was unknown to Saenz Egaña when he wrote his *Historia de la veterinaria Española*, which contains a recent (1941) history and bibliography of the early Spanish writers on the circulation of the blood, Montaña de Monserrat and Servetus It is possible that this edition was printed at Baeza in the province of Jaén, the title-page having a coat of arms with two lions and two castles which resembles that of Jaén The earliest surviving book printed in the town of Jaén is dated 1605, but at Baeza there was a printer Juan Bautista Montoya, between 1551 and 1594 He printed another book on horses—*Reglas de la Caballeria de la Brida* by Federico Grisone (1568)

Reyna gave as his motive for writing the *Libro de Albeyteria* the absence of any reliable work of a similar nature, and the existence of many misleading books which falsely stated that they were based on the teachings of Hippocrates and Avicenna. His book reveals a wise and modest man, of great experience, sound judgment, and alert observation He quotes Hippocrates, Guido de Cauliaco, Pliny, and Fray Yñigo de Mendoça, he also states that he has translated the works of Albertus Magnus from the Latin into Romance (the vernacular), but found them of little value Reyna has been dismissed by some Spaniards as an ignorant horse leech, but he belonged to a profession of the highest importance at a time when all land transport depended on good horses, before he was 26 he looked after the horses of the great Duke of Alva, who would not have chosen any but a man of reputation When at this early age he published his book he appears to have been regarded as the foremost exponent of the veterinary art of his time, but nothing further is known about him—except that he lived to an advanced age—and even his birthplace is uncertain it is thought to have been either Burgos or Zamora

Parliament

QUESTION TIME

Increase in Drunkenness

Mr CHUTER EDE, the Home Secretary, replying to a question, stated that the convictions for drunkenness in the Metropolitan police district during 1950 were 16,760 The comparable figure for 1946 was 9107 The figures caused him serious concern, and he was investigating the causes which could be assigned to them and what action if any, could be taken to reverse the position

Mr SOMERVILLE HASTINGS Is this unfortunate result found only in London or has there been an increase of drunkenness in other large towns?—Mr EDE I regret to say that such figures as I have been able to examine as a result of the reports of brewster sessions and so on indicate that this trend is prevalent all over the country

Prostitution in London

Mr EDE, replying to a question, said that a deputation, led by the Bishop of London, which he received, left with him a memorandum containing proposals made by the Paddington Moral Reform Council for dealing with the problem of prostitution in London, and he promised that it would be carefully examined. Until the examination was completed he could not say whether further inquiry by a departmental committee would be necessary If he decided to have an inquiry the necessary publicity would be given so that the widest possible range of evidence might be obtained

Mr SOMERVILLE HASTINGS Will the Minister make the terms of reference wide enough to include the problem of homosexuality ?—Mr EDE I have not yet decided that there shall be a committee but I shall have regard to the terms of reference

Protection against Smallpox from India

Mr THOMAS REID asked the Minister of Health what precautions had been taken to prevent the influx of smallpox from Calcutta where deaths from this disease now exceeded 500 a week —Mr ARTHUR BLENKINSOP replied Special care is being taken by airport medical officers, and travellers by air are given a warning notice Travellers by sea pass out of the incubation period for smallpox before they arrive Rigorous measures including if necessary the isolation of passengers, would be taken if a ship or aircraft were found to have a case of smallpox on board

Hospital Accommodation for Chronic Sick

Miss IRENE WARD asked the Minister of Health what steps he had taken to increase the beds for the chronic sick in the Northern Region —Mr BLENKINSOP replied A 30 bed unit has been opened, and the work on providing a further unit of 20 beds is almost finished

Waiting-lists for Sanatoria

Replying to a question Mr BLENKINSOP stated that in England and Wales at Dec 31, 1950 the estimated number of patients awaiting admission to sanatoria was 10 400

In England Now

A Running Commentary by Peripatetic Correspondents

WRIDDLE-ME-WREE

My size is small, my gait is of a hopper,
  My colour brown, it does not catch the eye
My name, though short, is not considered proper
  By the learned, and I often wonder why
Instead, they name me like the high and mighties,
Troglodytes troglodytes troglodytes

There's botany displayed upon the tanner,
  On the threepenny bit it urges one to thrift,
As one struggles with a dodecagonal spanner
  To extract it for a pourboire or a gift,
On the farthing, on the humble widow's mite is
Troglodytes troglodytes troglodytes

Though human kind may all conspire to mock me,
  I can well afford to disregard their sneer,
The fanciers of song-birds seldom stock me,
  For my voice is inconspicuous though clear
But there are fine games when the nights are Aphrodite's
For *Troglodytes troglodytes troglodytes*

* * *

Stimulated by Dr Ffrangcon Roberts's inquiries into the authorship of *Lancet* articles, I began to wonder what are the causes of the decline in acknowledgments to the family doctor in case-reports published by members of hospital staffs Is the extreme rarity nowadays of such acknowledgments merely a change in medicosocial custom, like the abandonment of the top hat and frock-coat ? Is it a reflection of the lessened financial dependence of hospital staffs on the general practitioner ? Or is it a symptom of a diminished collaboration between the hospital consultant and the G.P ?

These reflections were " pointed up " (as our American colleagues might say) by a recent report of a young man, earning his living and leading what he considered to be a satisfactory married life, who complained of symptoms suggesting a mild anxiety state and whose considerable surgical adventures left him with a prospect of endocrine therapy for the rest of his life—at a total cost to you and me of certainly more than £1000 The long list of acknowledgments at the end of this report did not include any reference to the family doctor, though one would have thought that the social aspects of the case could hardly have been dealt with satisfactorily without his collaboration Anyhow the family doctor will have to " hold the baby " and be primarily responsible for the aftercare—no light task Incidentally the " mild anxiety state " got lost in the general tohu-bohu and was not mentioned again Perhaps it is in the bottle with the other specimens in the pathological museum

The moral seems to be that it will be a pity if hospital staffs are not only going to ' Take the Cash " but " Take the Credit Too ' —if any What I should like to see among the acknowledgments is " and to Dr XY, the family practitioner, who did his best to keep the patient out of hospital "

* * *

As a registrar in the Department of Anæsthesia, I used to be regarded as (*a*) a member of the F D A (Failed D A) Club, and (*b*) an anæsthetist's mate The latter position is roughly equivalent to a plumber's mate, the main duty being to carry laryngoscopes and endotracheal tubes in the wake of one s chief It came as a surprise to my colleagues and other occupants of this large teaching hospital to discover that, owing to the searching examination for the modern D A., my character had developed some other facets

One of the theatre sisters, for example, collapsed in hysterical laughter when she saw me in the theatre corridor carrying a stethoscope Her comment was illuminating ' I didn t know you had one Can you use it ? ' Similar remarks emanate from the disrespectful medical students one sees around the wards nowadays when I attempt to organise the pre- and post operative care of patients Then the pathologists—defined by a surgical colleague as ' Men who smoke pipes and spit in the sinks "—gather in a bunch, like cartoon characters, and set their scented halls rocking with puckish mirth when I enter to find out just what did happen to that secondly it changes while it is thus diffused so that it can moisten these tissues Thirdly it changes while it is there so that it may repair and support any wasted parts It travels on and again separates the humours. Fourthly it changes since in any given place it soaks into the limb and takes on its character, that is in order that it may recover and restore, what gave it its heat, and use up the air, and repair the changes caused by a cruel world [i e, by wear and tear] "

TEACHING OF THE TIME

Reyna's anatomical views are highly traditional in most respects, the great exception being those on the circulation of the blood This is the more surprising by comparison with his teaching that the brain is a chimney for the smoke from the heart, expelling it through the eyes, nose, and mouth He describes digestion as taking place in four stages in the mouth, stomach, liver, and tissues, that in the stomach separates waste from nutriment, the latter (chyle) is carried to the liver, where it is coloured and is then distributed to the body according to its needs Blood is formed from the most "temperate" part of the chyle, the other humours from other appropriate portions If any chyle is formed in excess, it must be purged by the bowel, or by bleeding, or by dieting, or by other similar methods of depletion Purgation by the bowel should be regulated as a result of studying the blood removed at bleeding There are two kinds of blood the arterial or vital, and the venous or nutritive The arterial flows from the heart, the venous from the liver The seat of the spirit is the heart, it is vaporous, controlling movement, sensation, and warmth, and it is this spirit which is manifested in all the pulses

His pathological theories were the current humoral ones, he stressed the importance of a knowledge of anatomy in order that the humours responsible for any illness might be easily identified and abnormalities recognised Diseases being seasonal, a knowledge of the qualities of the humours and the seasons was required in order to appreciate the relationship But although the seasons were a factor he attached more importance to any form of excess, whether in eating, drinking, exercise, rest, or exposure to heat and cold The four qualities of heat, cold, wetness, and dryness, and their combinations are discussed in relation to the four humours Health consists of the right balance between qualities and between these and the corresponding humours—e g, heat and wetness, and the blood This concept is related to the four seasons, thus blood is dominant in March, April, and May which were, perhaps arbitrarily, classified as hot and wet—at least in Spain But the actual local quality of the weather at any season does not appear to have affected this seasonal classification

He compares the art of curing illness to the work of a gardener, who, finding an irrigation channel blocked, removes the obstruction and allows the water to flow to the plants He thus appears to subordinate the healer to the *vis medicatrix naturæ*, but in practice he does in fact advise a less passive rôle, this was inevitable in view of the long held and still prevailing view on the treatment of all diseases by the exhibition of their opposites

He was not wholly free from the influence of astrology (horses' tails should not be docked at certain seasons of the moon), or from alchemy (powder of lizards was of value, and so was an ointment made from certain black worms which emerged from the earth in May, June, July, and August, "as long as a finger," and had to be fried in oil), but in general he used such simple dairy produce as eggs and butter for dieting and for surface applications, and such vegetables and grain as would be found on any farm Qualities associating these products with the humours and the seasons indicated their appropriateness for any condition, thus butter is cold and wet, honey is hot and dry, yolk of egg is hot and wet Since all treatment was by opposites the horse-leech had an easy guide to prescribing, he need only remember that hot diseases must have cool medicaments. Plethora must be treated by bleeding

Thus, between much that is now known to be error, Reyna believed that the blood circulated, that in the course of that circulation it was diffused in the tissues, that it was associated with the warmth of the body, and that it gave off air Spain has never claimed for Reyna the discovery of the course that the blood followed and it need hardly be stated that no such claim is made for him here Prof H E Sigerist has inveighed with much eloquence against the present tendency, particularly in the English speaking world, to attribute paternity to every advance in medicine, every new discovery If such a protest needs any support, it is surely to be found in such books as the *Libro de Albeyteria* Reyna should be recognised as giving expression to a belief which, if not clearly defined, was evidently fairly widely held in 1546, since his book led to no protest

EDITIONS OF THE BOOK

The book was certainly first printed about 1546, the copyright—which was granted by Pedro de Loros on behalf of the King of Castile—being dated at Madrid, Nov 21, 1546 The title, *Libro de Albeyteria*, was used again in 1550 by Lopez de Zamora, suggesting that Reyna's book had achieved a success during the previous five years, which Lopez was quick to exploit

Although many editions have been recorded by Palau in his *Manual del Librero Hispano Americano*, there is one edition which has not previously been identified this is the edition of 1556 Palau cites the following editions 1546, 1552, Mondoñedo, 1553, Zaragosa (doubtful), 1564, Burgos 1580, Salamanca, 1582, Alcala, 1583, Alcala, 1603, Alcala (first annotated edition), 1617, Madrid, 1623, Alcala, 1647, Alcala The annotated editions of his work were probably published after his death There are copies of 1603 and 1623 editions in the British Museum The notes are by Ferdinand Calvo, and although he doubtless improved the purely veterinary part of the book, he seems to have regarded Reyna's description of the circulation of the blood as irrelevant He omitted the sentence about the heart being "the emperor of the body" from the 1603 edition and suppressed the whole description from subsequent editions

A copy of the first edition is in New York, in the possession of the Hispanic Society of America, and is stated to have been printed at Burgos Two copies of the Mondoñedo edition have survived, one at the Hispanic Society, the other in the National Library, Madrid, and the British Museum has a copy of the 1580 edition in which the colophon is incorrectly dated 1570 No copy of the doubtful 1553 Zaragosa edition is known In the library of the Royal College of Physicians there is a copy of the edition of 1556, which has never been recorded, and of which this is therefore likely to prove the only surviving copy It is a revised edition, priced at two maravedis a copy Certain pages are missing, but were made up in manuscript in the late eighteenth century, or a little earlier The copyist states that he had before him a Zaragosa edition printed by the Casa de Lorenzo y Diego de Robles hermanos in 1583, and that he considers the 1623 Alcala edition superior to this 1583 edition, but wishes to use the earliest one available to him

The 1556 edition was unknown to Saenz Egaña when he wrote his *Historia de la veterinaria Española*, which contains a recent (1941) history and bibliography of the early Spanish writers on the circulation of the blood, Montaña de Monserrat and Servetus It is possible that this edition was printed at Baeza in the province of Jaen, the title page having a coat-of arms with two lions and two castles, which resembles that of Jaen The earliest surviving book printed in the town of Jaén is dated 1605, but at Baeza there was a printer, Juan Bautista Montoya, between 1551 and 1594 He printed another book on horses—*Reglas de la Caballeria de la Breda* by Federico Grisono (1568)

Reyna gave as his motive for writing the *Libro de Albeyteria* the absence of any reliable work of a similar nature, and the existence of many misleading books

Nevertheless, the use of noradrenaline to combat hypotension in man would seem to be justified for the present on the following grounds

1 Noradrenaline differs from adrenaline in that its administration seems less likely to be followed by a depression of sympathetic vasomotor tone Whereas infusions of adrenaline in man are followed by peripheral vasodilatation,[2] similar infusions of noradrenaline are not followed by vasodilatation (unpublished observations)

2 Studies in this hospital on the effect of noradrenaline in methonium hypotension indicate that its use is not followed by a further fall in blood-pressure (Churchill-Davidson)

3 Noradrenaline increases the blood-pressure by increasing the peripheral resistance, adrenaline by increasing the cardiac output[3] As methonium hypotension is due to decreased peripheral resistance, it would seem reasonable to give noradrenaline rather than adrenaline

4 Pitressin would also elevate the blood-pressure by a constrictor action on the vessels But, as Professor Burn points out, it has the disadvantage of constricting the coronary vessels Its action in this respect is unfortunate, for the object of raising the blood-pressure is to improve the coronary and cerebral blood flow The action of noradrenaline on the coronary vessels in man is not known In animals, however, noradrenaline dilates the coronary vessels.[4]

DOSAGE OF METHONIUM COMPOUNDS

SIR,—Several correspondents have stated that they start the administration of methonium compounds with an intramuscular injection of 50 mg I have found in one case recently that this was too large a dose since it produced an unpleasantly great fall in blood pressure

Pentamethonium bromide 50 mg was injected intramuscularly into a woman whose initial blood pressure was 260+/135 mm Hg The pressure fell to 120/70 in ten minutes, and to 100/60 in eighteen minutes The patient was recumbent but nevertheless felt faint Adrenaline 5 minims was given intramuscularly on three occasions, and one hour after the injection of pentamethonium the pressure had risen to 145/80, with the patient feeling comfortable

In my opinion, 25 mg is quite enough to give as an initial intramuscular injection in cases with this degree of pressure

It is of interest to note that after the intramuscular injection of adrenaline there was an interval of about three minutes before the pressure rose, and that it fell again within a few minutes after each of the first two injections. After reading Professor Burn's letter in your issue of March 17, I should try pituitary extract, although I should be inclined to inject it intramuscularly since this would be easier and quicker than setting up an intravenous drip

Dorchester　J HERBERT BURNS

UNFAIR QUESTIONS

SIR,—The following suggests a line of approach that commonly succeeds when one is confronted with a ridiculous question

I remember being asked in a clinical oral to diagnose a condition which is so rare as not to be mentioned in any of the standard textbooks of medicine Having been told by the patient what he was suffering from, I presented the right diagnosis When he had recovered the examiner not to be outdone, said, how do you treat it ? Not having the slightest idea and playing for time, I replied well, there are several different ideas about the treatment", to which the examiner rejoined yes, there are some new fangled notions ' 'But I prefer the good old fashioned treatment,' I retorted, and to my delight the examiner said, "yes so do I, let's go and see the next case" One wonders if the examiner himself knew the answer to his own question.

It is surely high time that oral and clinical examinations were devised to fulfil the purpose for which they were intended—namely, to find out if the candidate is a suitable person to practise medicine, instead of being at best a humorous diversion and at worst an opportunity for the examiner to show off his own knowledge It would be interesting to hear what the examiners themselves have to say

Bournemouth.　G V JAFFÉ

CORONARY DISEASE AND MODERN STRESS

SIR,—All your correspondents appear to agree that "modern stress" is a large factor in the ætiology of coronary occlusion Why then is this so much more common in men than in women, as is all occlusive vascular disease ? Surely during the last thirty years, and especially during the war years, women have had more "stress" than men.

Buxton　F A BEARN

MYXŒDEMA FROM RESORCINOL OINTMENT

SIR,—Bull and Fraser[1] threw much light on this condition, and several other cases have now been described[2 3] The causation was confirmed by Doniach and Fraser,[4] but was disputed by Klein et al.[5]

The *National Formulary*, 1949, includes (p 100) ung. resorcinol and ung resorcinol co, the first containing 4% and the second 12% resorcinol The unnamed proprietary preparation incriminated by Bull and Fraser[1] and by Hobson[3] contains 4% resorcinol.

I recently performed a necropsy on one such case This was of an elderly woman who had had leg ulcers for 20 years and died of myxœdema with a very large goitre histologically free from any suspicion of colloid Many more cases of this syndrome are to be expected, it can result from the exhibition of sulphonamides, thiocyanates, thiouracil, and cabbage leaves in addition to resorcinol, and perhaps also from other drugs at present unsuspected Would it not be a good idea to remove the two resorcinol containing ointments from the *National Formulary*, and to persuade the manufacturers of the anonymous proprietary preparation to remove resorcinol from their formula ?

DIPHTHERIA ANTITOXIN IN CORD-BLOOD

SIR,—Miss Barr and her colleagues, in their article of March 31, have produced just such another valuable contribution to our knowledge of infant passive immunity as one would have expected from them

One does, however, feel that they take a slightly pessimistic view of future possibilities in respect of immunisation of the very young infant which possesses quantities of maternally bestowed antitoxin in excess of 0 04 unit per ml Perhaps it would be more correct to say that one finds no particular note of optimism in this respect This may be justified if Miss Barr and her associates are only prepared to think in terms of A P T as the prophylactic to be employed

To those of us who feel that the future of safe and effective immunisation lies in treating the infant of from 2 to 5 months, the mind turns from the use of A P T to a concept of some form of prophylactic which will provide an adequate primary stimulus in the face of fairly considerable quantities of maternally endowed antitoxin The section "Age at which immunisation transthoracic gastrectomy The radiologists (believe it or not) switch on lights and even remove their goggles when I hazard a staccato “ Atelectasis, isn't it ? ” The Director of the Clinical Laboratory actually signed the report himself after I had consigned to his department an ampoule containing the remnants of some intravenous barbiturate solution with a request that he would try to persuade something to grow in it Most surprised of all was the Lecturer in Public Health when I showed desperate interest in the investigation of an outbreak of diphtheria in an institution, or perhaps it was the Biochemist after I had plagued him with questions on abstruse blood-investigations

* * *

I was a trifle suspicious when I heard at my outlying surgery that the vicar's wife was asking whether the doctor kept any scales in the surgery When later, from the window of a patient's house in the village, I saw the vicar's wife, accompanied as usual by her two terriers on leash, coming my way, I was certain from the look in her eye that something was afoot Sure enough, as I reached the car, she suddenly turned round from walking aimlessly down the road and said “ I see you have some scales in the car I wonder if you should weigh me and then the dogs ? You see, they both have worms and I nearly killed them last year by giving them an overdose of medicine ”

I am used to casual consultations in the street, but I was taken aback by this calm assumption that dog-weighing is among the facilities offered by the N H S However, being also anxious not to cause speculation in a village notorious for its gossip, I asked “ Where shall we go ? To your house ? ” “ Oh, no,” said the vicar's wife, “ here will do quite well ” Bemused and a bit abashed I took out the scales and proceeded to weigh the lot She did thank me, so though I wanted to tell her that the Health Service does not cover pets, I held my peace My fee for the roadside consultation came later and in an unexpected form—a pot of lime honey

* * *

After the meeting we left York on time and sped south through the darkness, and well we might since we were pulled by the great Pacific locomotive *Gay Crusader*, worthy namesake of speed in another sphere We covered mile after mile without faltering, then somewhere in the wilds the train gradually slowed down and stopped It was only a blown out headlamp, but rules must be observed even by the famous And it, would have been a trifle undignified if *Gay Crusader* had ignored the fault and gone on to London with only one headlight, for a single light, according to its side, is the sign of either a universal train or ballast train stopping at all stations

Aphorism of the Week

Babes stand asphyxia as adults stand decapitation

Letters to the Editor

GENERAL PRACTITIONER AND CONSULTANT

SIR,—On every side one hears of the falling status of the family doctor and general practitioner With this it would appear that a gulf, which is widening rapidly, has developed between the hospital doctor and his colleague in general practice The causes are no doubt multiple and different, but the effect upon medical practice in the future cannot be anything short of disastrous

Many of the immediate difficulties are no doubt related to finance, and many of the suggestions which have been made—suggestions which would go far to improve the present situation—are impracticable I refer particularly to facilities whereby general practitioners would be able to continue the treatment of certain of their own cases in general hospital beds The impossibility of realising this aim for the time being should not deter us from doing what can be done to relieve the threatening situation. With this end in mind, I have wondered whether it might not be possible for consultants and specialists to be placed in a position where they would be able to request a consultation with the patient's family doctor, the consultation to take place in the hospital wards or outpatient department Such an arrangement would frequently be of great value to the patient, and would at the same time introduce the general practitioner to the inside activities of the hospital Before long he would be welcomed by sisters and nursing staff, who would realise, to their own great benefit, the important position which should be held by the family doctor in the general pattern of investigation and treatment.

To put such consultations upon a firm and proper basis, it would be necessary to pay the general practitioner a suitable fee for his services The total cost of such an arrangement would be fully justified, and would before long be paying big dividends in the all round improvement which would result, not only in the care of the patient, but in the relationship between specialist and general practitioner

One would like to go even further than this, and hope that an arrangement might be possible whereby the attendance of general practitioners at domiciliary consultations was also adequately remunerated It is surely no part of the busy and overworked doctor's terms of service that he should devote an hour of his time watching his hospital colleague carry out an extensive neurological investigation upon one of his patients The value of such attendance is obvious enough, but the sacrifice in time should be remunerated Would it be even worth reducing by, say, 25% the consultant's fee, in order to pay the family doctor—if the money cannot be found in any other way ?

The threat to medicine by the present difficulties is real and great Unless we are prepared to make some sacrifice in order to neutralise this threat we may find that we are too late These suggestions are put forward with hesitation and humility They appear to be practicable, and likely to go some way towards safeguarding the profession for the future

NORADRENALINE IN HYPOTENSIVE STATES

SIR,—In his letter of March 17, Prof J H Burn advised against the use of adrenaline to combat hypotension due to methonium compounds, on the ground that its administration is likely to be followed by a further fall in blood pressure due to its ganglion blocking action [1] Noradrenaline is said to have the same action in this respect curve In the larger series the site of perforation is not discussed, but I believe that the upper part of the stomach is the more commonly injured

---

[1] J Physiol 1942 101 289

Schindler advises blind and rapid penetration of his instrument to his position I, from which the pyloric antrum can be viewed, on the grounds that the stomach is taken unawares and the gastroscope is not detained in the upper half of the body by hour glass contraction, which may occur if a more cautious descent is made Since resistance to the passage of the gastroscope cannot be taken as a warning of impending perforation, it must surely be safer to proceed from the cardia to the pyloric end slowly and with caution, despite the long delays that such a technique involves

Reference is made in both papers to occasional difficulty in overcoming resistance at the pharyngo-œsophageal junction At the suggestion of Dr W J Walkden, some months ago when experiencing this difficulty I employed a capsule of amyl nitrite crushed under the patient's nose, and within a few seconds the gastroscope passed effortlessly downwards I have since used this technique, with success, whenever encountering resistance either at the upper or the lower end of the œsophagus

Most observers of the British stomach will surely agree with Dr Avery Jones that the appearances "supposed to indicate" gastritis bear no consistent relationship to clinical findings except perhaps in pernicious anæmia

Wolverhampton J V S A DAVIES

WILL WE NEVER LEARN ?

SIR,—Now that correspondence has been appearing for some weeks, may I ask that the title "Will we never learn ?" shall be corrected to "Shall we never learn"? These foreign idioms in English journals are very confusing for the natives

Bristol E WATSON WILLIAMS

⁂ But is it a foreign idiom ? The author of this phrase (as we understood him) chose "will" because it conveyed an element of intention—or rather lack of intention We tried the effect of substituting the pure future form, but "Shall we never learn ?" seemed a trifle anæmic as a heading for what followed

We take this opportunity of acknowledging a small inaccuracy in a leading article of March 24, in which Scotland was described as England —ED L

BACTERIAL VARIANTS PRODUCED WITH CHLORAMPHENICOL

SIR,—I should like to answer the points raised by Dr Rogers in his letter of March 10

(a) I certainly agree that non catheter specimens might be contaminated This is why the alterations in bacterial morphology observed in micro organisms isolated from patients under chloramphenicol treatment were attributed to the drug only after in vitro experiments had proved that similar alterations could be obtained by the combined action of antiserum and this drug Moreover, although most of the abnormal bacteria were identified as belonging to the same species as the original infecting organism, the need for verification was the only reason for which the in vitro experiments were done

(b) Dr Rogers wrongly assumes that the serum of the patients had no agglutinins Case 4, the only one in which serum agglutinins were sought, had a serum agglutinin titre of over 1/800 Dr Rogers also accepts too lightheartedly that cases with urinary infection do not develop agglutinins Baird,[1] investigating 69 cases of pyelitis, found agglutinins in the serum of 30 He emphasised that the agglutinins were specific for the organism in the urine, and that in most of them the agglutinin titre of the serum was very high (1/2000) When, however, I spoke of "special conditions in the body" this meant any immunological reaction of the serum, of the cells, or of the tissues, as well as any changes that chloramphenicol might have suffered in the body Indeed this last possibility had been the first to be investigated However, only the one hypothesis that eventually proved to be right was described, in a serious effort to conceal how "painstaking" this work had been After Dr Rogers's letter I see how much I have failed in this effort

(c) Dr Rogers objects to my nomenclature of the variants, but surely it is not wrong to describe the three children of *Bact coli* D433 as variants α, β, and γ This simply means 1, 2, 3 or a, b, c, and has nothing to do with Stamp and Stone's alpha antigen Letters of the Greek alphabet are commonly used in all scientific fields I feel most distressed at the thought that I might be deprived of the use of some letters of my own alphabet because priority might be claimed by workers who have already used them

INDUSTRIAL HEALTH SERVICES

SIR,—In your interesting leading article of March 10, dealing with the Dale report, you say that in the U S A health engineers "are now maintaining that in order to deal with industrial health it is unnecessary to have a medical qualification" This is not in accord with the facts

The preservation and improvement of the health of workers in industry is a task to which different persons make their contributions—e g, the doctor, the engineer, the welfare worker, the safety officer, and the nurse It is impossible for a medical officer to deal alone with the prevention of hazards involved in existing and in newly adopted processes in a plant Equally it cannot be expected that the health engineer shall know where pathological conditions may arise in man owing to such exciting causes as dust, high temperatures, excessive humidity, and the many toxic substances involved in modern industry Nor can the engineer adequately assess the conditions necessary to maintain optimum health among the workers in any factory

The advent of the health engineer is a progressive step in the constant endeavour to improve the health of those engaged in industry, and so indirectly to contribute to a higher standard of physical and mental fitness in the population as a whole, and it in no way displaces anyone from the health team Your article calls attention to the group industrial health services at Slough, to which there has been appointed an industrial health engineer who works in close coöperation with doctors in providing a genuinely preventive industrial health service

I have an intimate knowledge of the valuable contribution made by the industrial health engineer in the U S A A conspicuously successful example of the value of such team work is to be seen in the highly successful development of the area controlled by the Tennessee Valley Authority It would be fatuous to expect a doctor alone to institute the many measures for the prevention of malaria that have been successfully adopted there by teams consisting of doctors, chemists, entomologists, and public health engineers Similarly, in industry in the U S A the preventive aspects of industrial health have been dealt with successfully by a team consisting of doctor, industrial hygiene engineer, and chemist Since the maintenance of health is the main problem of the team it is almost invariably the doctor who leads the members of the team, and he is not, as your article suggests, supplanted by the engineer

In order that the work already being done in this country by some engineers should be even more effective, it is desirable that they should have a specialised academic could be started" defines a limit which I, for one, am not prepared to take lying down. I believe that the trouble can, and will, be overcome, and I am working to that end.

---

[1] Baird D *J Obstet Gynæc* 1935 42 577

The final paragraph in the summary is perhaps a little ambiguous. It runs: "The Schick test would give little useful information as to when immunisation could be started in the babies with expectation of success." I presume that this means that simple Schick testing of any given population would be no sure guide, for in the individual infant the answer is not in doubt. They regard 0.004 unit per ml. as approximately the Schick positive level, while interference with the primary stimulus is stated by them not to occur at levels of about 0.04. You can, of course, immunise infants at any age by first doing Schick tests and then administering prophylactic only to the positives. I believe that you can do much more than this.

As a piece of thorough and painstaking research on cord blood, this article will be widely welcomed, and the authors are greatly to be congratulated.

London S.E.5 GUY BOUSFIELD

PSYCHIATRIC ASPECT OF ORGANIC DISEASE

SIR,—In his article last week, Dr. Todd states that in treating cases of chronic arthritis "the essence of the doctor's task should be to put the onus of recovery upon the patient," and that "any pre-existing ideas" that various forms of physiotherapy "are necessary should be vigorously suppressed." May I suggest that the pre-existing idea that the use of the hospital car service is necessary should be included in this vigorous suppression?

St. George's Hospital
London, S.W.1

B. D. SPENCER
Almoner

THE ECONOMIC VALUE OF THE DOCTOR

SIR,—Dr. Ffrangcon Roberts, by his frightening article (March 24), has performed a signal service in focusing our attention on a problem hitherto suppressed in the minds of many of us.

The time has come for everybody, including auxiliary hospital personnel, high-powered scientists, and particularly politicians, to answer the question: "What is a health service?" It is time, too, for public-health officers to admit that, however much they "prevent," somebody, somewhere and some time, will fall ill. It is the diagnosis and treatment of the sick individual that should form the basis of any health service—not because the patient is a key man in industry, not because the family may suffer, not because he is a cog in the economic machine of the community, but simply and solely because he (or she) is ill.

For let us be quite clear—when a person becomes unwell he turns to the doctor. A history has to be taken—a more difficult, skilled, and accurate diagnostic measure than all the chemical and electrical paraphernalia in use today—and then the patient has to be examined. In these two procedures lie the knowledge, experience, judgment, and art of medicine. Scientific aids to diagnosis are not of the slightest use until the doctor has decided when and where to use them and how to interpret them in relation to the patient. Furthermore, therapists, administrators, statisticians, and the rest could stay at home for all the good they would do in the absence of a doctor. If one has a patient, a doctor, and—may I add—a nurse (sadly neglected in the scramble for cash and kudos) one has a health service. Without these one has nothing. Lashings of preventive medicine and statistics, nice filing systems, plenty of equipment, therapists by the dozen, and marvellous diets would become to the sick man worse than a mockery. This, then, is the functional and economic position of the doctor—and may no one forget it.

Inchture, Perthshire A. HUGHES

PUBLICITY IN CANCER

SIR,—In his letter last week Dr. Horace Joules refers to the report by Doll and Bradford Hill as "passed unnoted by the non-medical press of this country, and, in fact, there is evidence to suggest that publicity has been withheld." I am sure that in fairness to the lay press you will allow me to say that this report was in fact referred to in *The Times* of Sept. 29, 1950.

EFFECT OF A.C.T.H. ON RENAL GLUCOSE THRESHOLD

SIR,—Adrenocorticotropic hormone (A.C.T.H.) has been found to induce glycosuria,[1] and this has been assumed to be caused by a lowered renal threshold for glucose. However, no study of the renal threshold for glucose after administration of A.C.T.H. in "renal diabetes" has yet been undertaken.

We gave two injections of A.C.T.H. to a patient with renal diabetes (one day 36 mg. and another day 24 mg.). Endogenous creatinine clearance, tubular reabsorption of glucose, tubular glucose reabsorption index, and renal threshold for glucose were determined both before injection and 60, 120, 150, 180, 210, and 240 minutes later. Analysis of the data revealed a small fall in plasma creatinine, with no consistent change in urinary creatinine; creatinine clearance was increased. Tubular reabsorption of glucose, tubular glucose reabsorption index, and renal threshold for glucose were significantly increased by A.C.T.H. More consistent changes followed the larger dose of A.C.T.H.

These findings do not agree with earlier reports suggesting that A.C.T.H. lowers the renal threshold for glucose. Additional studies are desirable in order to determine whether our results are related to any particular condition in renal diabetes. Further details of this work are to be published in *Folia Endocrinologica*.

V. DE FILIPPIS
A. IANNACCONE

THE RISKS OF GASTROSCOPY

SIR,—In your issue of March 24, Dr. Avery Jones and his colleagues appear to show that perforation of the œsophagus, particularly in its upper part, is the chief risk of gastroscopy. Only 9 cases of gastric perforation were recorded among about 49,000 gastroscopies. Yet in a companion article Dr. Boon cites 4 cases out of 4000, 3000 of which (though we do not know how many gastric perforations) are included in the analysis of Dr. Avery Jones. Dr. Boon's gastric perforation rate was at least five times, and possibly nine times, higher than that which is supposed to have occurred in the larger series.

This discrepancy, which must surely be significant, is open to various interpretations. It is improbable that the technique employed by the various other gastroscopists differed materially from that of Dr. Boon, or that the cases subjected to gastroscopy were more carefully chosen. Dr. Boon stresses the difficulty he experienced on two occasions in convincing his surgical colleagues of the fact of perforation. Dr. Avery Jones himself implies that in his series "mild cases" may have been overlooked, and it may well be that gastric perforation is a far more common complication of gastroscopy than his figures appear to show. In the 3 cases of Dr. Boon which came to operation, perforation was found in the upper part of the posterior wall close to the lesser

Public Health

Statistics for 1950

According to provisional figures issued by the Registrar-General,[1] the birth-rate in England and Wales during the year 1950 was 15 8 per 1000 home population, this was 0 9 below the rate for 1949 The illegitimacy-rate was 49 per 1000 live births—15 per 1000 below the average for the preceding five years The provisional stillbirth-rate was 22 6 per 1000 total live and still births, compared with 22 7 for 1949

The death-rate was 11 6 per 1000 home population, this was 0 1 less than that for 1949 Infant mortality was 29 8 per 1000 related live births and was the lowest ever recorded in this country, the rate was 2 4 below that for 1949, the previous lowest

Births exceeded deaths by 182,148, the corresponding increase for the preceding year was 210,479, and the average for 1944–48 was 290,783 The estimated total population for the year was 44,020,000—an increase of 235,000 over the estimate for 1949 The estimated home population was 43,830,000 The effective reproduction-rate, corresponding to the births in 1950 and allowing for continuing improvement in survivorship conditions, is provisionally assessed at 0 98, indicating that births were 2% below those required by a par replacement standard This is the first year since 1945 that the rate has fallen below unity

Population Estimates—The Registrar General has issued estimates of the population of each administrative area at June 30, 1950[2]

SCOTLAND

In Scotland the birth rate in 1950[3] was 17 9 per 1000 population—0 6 below the rate for 1949 The illegitimacy-rate was 52 per 1000 live births The stillbirth-rate was 27 per 1000 total births—the same as in 1949

The death rate was 12 4 per 1000 population—0 1 above the rate for 1949 Infant mortality amounted to 39 per 1000 live births, this rate, the lowest ever recorded in Scotland, is 2 below that for 1949, and 11 below the five years' average The neonatal death-rate was 23 per 1000—the same as that for 1949, which was also the lowest ever recorded for Scotland. The death-rate from tuberculosis (all forms) was 54 per 100,000—21 below the five years' average The rate for deaths from respiratory tuberculosis was 47 per 100,000, and from non-respiratory tuberculosis 6 per 100,000, these two rates are 15 and 6 below the five years' average

The natural increase for the year was 28,532, compared with an average of 36,517 for the previous five years

Postinfectious Encephalitis

Up till the end of 1949 encephalitis was notifiable only under the heading "encephalitis lethargica" From the start of 1950, however, encephalitis has been notifiable as either "infective" or "postinfectious", and under the latter heading altogether 71 cases were notified in England and Wales during the year

Reviewing 65 of these 71 cases, Conybeare[1] remarks that in 6 the disorder, was subsequently judged to be poliomyelitis, in 8 the association with an infectious disease could not be substantiated, and in 10 the diagnosis was eventually changed In the 41 remaining cases the associated diseases were as follows measles, 15, mumps, 10, chickenpox, 9, influenza, tonsillitis and pharyngitis, vaccinia, 2 each, and rubella, 1

Campaign Against Diphtheria

In the last ten years over 9 million children in England and Wales have been immunised against diphtheria, and deaths from the disease dropped from 2480 in 1940 to a provisional 85 in 1949 The improvement continued in 1950 and provisional figures show that there were only 32 deaths from diphtheria in the first half of the year compared with 53 deaths in the same period of 1949 These figures would give every reason for satisfaction were it not that this immense reduction in the incidence of the disease has made parents less aware of its dangers This is shown by the fall of 27,000 in the number of immunisations carried out in the first half of 1950 compared with same period in 1949 Drawing attention to this setback in the immunisation campaign, the Ministry of Health have asked all local authorities to arrange for intensive publicity and propaganda to call the attention of the public to the importance of diphtheria prophylaxis, and have set as the target for 1951 the immunisation of 75% of babies—more than 500,000—before their first birthday

Obituary

CHARLES RICHARD BOX

M D B.Sc. Lond, F R C.P, F R.C S.

Dr C R Box, consulting physician to St Thomas's Hospital, the London Fever Hospital, and the Royal Masonic Hospital, died on April 3 at the age of 84

From Dulwich College he entered St Thomas's Hospital in 1884, where he rounded off a brilliant career as a student by taking honours in physiology, medicine, and obstetrics in the M B examination, qualifying in 1892 At St Thomas's he was appointed successively to the posts of medical registrar and resident assistant physician at a time when each was held for three years During these formative years he found time to take the higher qualifications of M.D, M.R C P, and F.R.C.S He was thus exceptionally well qualified when he was appointed to the staff as physician to outpatients with charge of the children's department

[Lafayette

It was then the exigent custom for each assistant physician, as well as attending outpatients on two days a week, to do post-mortems on another two days But Box did even more, for he continued to act as demonstrator in anatomy for some years after he had been appointed to the full staff in 1915 Indeed, he only gave up this work when the department was reorganised after the war This experience formed the basis of his useful and lucid *Manual of Morbid Anatomy and Post Mortem Technique*, which, like all his infrequent writings, was backed by wide experience and accurate observation *Clinical and Applied Anatomy*, which he wrote with McAdam Eccles, was no exception to this rule, for Box lectured at the medical school for many years on anatomy background and should appreciate the health problems involved. The postgraduate course in public health engineering which is now being held in London is recognition of the fact that personnel should preferably be trained rather than that they should learn only from experience gained on the job.

IS OBESITY AN ENDOCRINE PROBLEM?

SIR,—I read with interest your annotation last week. Dieting seems the best remedy for obesity, but it is difficult to apply. If indeed overeating is associated with personality factors, the nervous breakdowns that occasionally follow dieting may be due to the same factors. On the other hand, I have seen undesirable gain of weight rectified during prolonged treatment for severe anxiety state, because of the change of habits following the mental improvement, this implies both less eating and more productive activity. Slimming cures such as those on the television programme and in journals differ from ordinary private dieting through the atmosphere of group therapy involved.

London N W 4 — S LOWY

BORSTAL FOR GIRLS

SIR,—May I add some figures to your footnote on Mr Bell's letter last week with regard to the "care and protection" cases that end up in borstal after absconding from an approved school?

According to figures given in the House of Commons by the Home Secretary in May, 1949, there were 23 "care and protection" cases in the girls' borstal institutions, *excluding* those beyond control and those showing criminal tendencies. Considering that the daily average population in the girls' borstals in 1949 was only 221, this figure is startling.

The Criminal Justice Act gave the Secretary of State the power to establish special approved schools for absconders, whether "care and protection" cases or delinquents. The above figures show how urgently needed such a school is in the case of girls.

MATERNITY AND THE ADMINISTRATOR

SIR,—It is very difficult to understand what Professor Nixon means. In his letter (March 31) who is "the administrator?" Does he think that the secretary dictates the policy and resolutions of the London Local Medical Committee? Does he know that the majority of the members of the committee are engaged in active general practice? Does he know that the committee at its meeting in February, "gravely concerned at the number of patients who have died in London this year because hospital beds could not be found for them in time," called on the Minister of Health "to take *all* possible steps to remedy the bed shortage" (Unlike the majority of the lay press, THE LANCET omitted to quote the main part of the resolution.) Does Professor Nixon also know that the committee has asked the consultants' organisation to appoint eight representatives, that only four have been appointed, and that the fact that there are no obstetricians on the committee is therefore entirely due to their own neglect?

Even your brief extract made it plain that the committee regards unsuitable housing conditions, *when properly established*, as warranting the hospitalisation of an obstetrically normal confinement. What about the "other conditions" necessary for a home confinement? Cannot the hospitals of London supply the full resources of a modern obstetric service, including a "flying squad?" Lastly, what evidence has Professor Nixon that it is better for a normal confinement to take place in hospital rather than at home?

In its statement to the press this committee pointed out that in the present shortage of beds it was a case of choosing how they should be occupied—by normal confinements or the acutely ill. It seems that Professor Nixon has made his choice. He asks the age and condition of the patients who died. The conditions were chiefly pneumonia and cardiac failure, and admittedly the age of the majority (though not of all) was over 50. Is Professor Nixon saying "let the old people die?" If he is saying so, then let him realise that he is advocating a return to barbarism.

Tavistock House
London, W C 1

F GRAY
Secretary Local Medical Committee
for the County of London.

*** Dr Gray complains that "unlike the majority of the lay press" we published only a brief extract from the committee's resolution. The explanation is simple: unlike the lay press, we did not receive a copy.—*Ed. L.*

SIR,—Arising from Professor Nixon's warning on this subject, in his letter of March 31, I think that the time has come to measure the maternity services of the country against the ideal visualised by the Royal College of Obstetricians and Gynæcologists, and even against that referred to in section v of the *Development of Consultant Services*.[1]

How many of our towns possess any obstetric service worthy of the name? It would be profitable to learn how many hospital groups have only nominal cover of two or three consultant sessions in order to satisfy the administrator's statistics, whilst the consultant himself may reside some distance from the area. It is common knowledge that scores of members of the college are without hope of obtaining an appointment suited to their training, whilst their chances of entering general practice are just as remote.

Shirley Croydon — J C MILLER.

SALICYLATES AND CORTISONE IN RHEUMATIC DISEASES

SIR,—In your leading article last week, I am quoted as saying that salicylate has an effect on healing when judged by standard skin wounds in mice. I did not, in fact, say this, and did not give any observations on salicylate at all, as I have never used it. Professor Buttle, however, has tried salicylate, using our technique, and found that it does *not* inhibit healing.

My observations on γ resorcylate have been quoted correctly.

St Thomas's Hospital
London S E 1

BARBARA E CLAYTON

MUNCHAUSEN'S SYNDROME

SIR,—I was interested to read Dr Rosemary Bolam's account of the second patient described by her in your issue of March 31.

This man volunteered that his father, an hotelier, served in the Scots Greys. He at first stated that he himself was a 4th year medical student, but subsequently revised this estimate to $2^1/_2$ years. He said that he had been able to enter Glasgow University "through friends." He "did some hospital work" but was "more or less in laboratories." He could not recall what examinations he took. Dr Bolam describes him as an ex Commando, but she omits to mention his transfer from the Royal Artillery to the 1st Airborne Division and his exploits at Arnhem. Attaining the rank of sergeant he served in many theatres, including the Near, Middle, and Far East, not to mention Italy, but disliking "red tape," "I threw my medal ribbons into the fire." He said he had travelled to Liverpool from Glasgow by rail via York—an unusually circuitous route, one might think.

Truth is stranger than fiction, but romance, too, has its charm, even if it only reveals the kind of people we should like to have been, and the deeds we would fain have wrought.

Liverpool — S BARTON HALL

Central Council for the Care of Cripples

The annual general meeting of the council will be held on Friday, April 20, at 2 45 P M. in the Goldsmiths' Hall, Cheapside, London, E C 2, when Mr Hilary Marquand, the Minister of Health, will speak

Shortage of Sulphur

The Ministry of Health has issued the following statement .

" Doctors will be aware of the shortage of sulphur and sulphuric acid, both of which are indispensable to the manufacture of a wide range of medical supplies Every effort will be made to maintain supplies at as high a level as possible to meet medical needs, but it is nevertheless essential if shortages of vital products are to be avoided that every economy (consistent with the needs of their patients) should be exercised by doctors both in hospitals and in the general practitioner services in the ordering or prescribing of all substances where sulphur or sulphuric acid are used during manufacture It may not be generally known how wide a field this is Broadly speaking, the types of drugs and medical supplies concerned are antibiotics , barbiturates , bromides , citrates , preparations containing glycerine , hormones lactates , salicylates (including all forms of aspirin) , preparations containing spirit , sulphates of barium, iron, magnesium, and sodium , sulphonamides , tartrates , vitamins , dressings (most types) , and photographic hypo

World Health Organisation

Spain and the German Federal Republic have applied for admission to the World Health Organisation Their request will be placed on the agenda of the fourth World Health Assembly opening in Geneva on May 7 Another candidature, that of Japan will be examined at the same time Total membership of W.H O is now 76, including Southern Rhodesia as an associate member Of these, 10 member States are considered as inactive

Osler Club of London

The following officers have been elected president, Mr Zachary Cope , vice presidents, Dr A P Cawadias and Mr Geoffrey Keynes general secretary, Dr W R Bett , librarian, Mr J Thornton treasurer, Dr A White Franklin , members of council Mr W J Bishop Dr L Carlyle Lyon, and Mrs Hipkins The club is open to students, doctors, and medical library workers, and further information may be obtained from the secretary 11, the Avenue, Chiswick, W 4

Kathleen Schlesinger Fellowship

The Medical Research Council invite applications for this whole time fellowship (£700–£1000 per annum), tenable at the National Hospital for Diseases of the Nervous System, Queen Square, London, W C 1, for work on cysts of the brain Preference will be given to candidates who elect to work on the mechanisms underlying degenerative processes affecting the brain Further information may be had from the secretary of the council, 38, Old Queen Street, London, S W 1, to whom applications should be sent not later than May 31.

Election to G M C

Last Tuesday voting papers were sent to all doctors registered as residing in England Seven vacancies are to be filled by direct representatives of the medical profession in England and these are the following eight candidates to choose from

NOMINEES OF BRITISH MEDICAL ASSOCIATION

Dr R H B BARROW of Winchester member of the G.M.C. and of the central ethical committee of the B.M.A for 6 years.

Dr J A BROWN of Birmingham member of the G.M.C since 1947 chairman of the representative body 1949–50 and member of G M.C of the B M.A

Dr O C CARTER of Bournemouth member of the G M.C since 1949 and member of council of the B M.A

Dr H GUY DAIN F R.C.S of Birmingham member of the G M C since 1934 chairman of the representative body of the B M A 1937–42 and of council of the B M A 1943–49

Dr E A GREGG of London member of the G M.C since 1942, chairman of the representative body of the B M.A 1948 chairman of council of the B M.A since 1949 and chairman of the Insurance Acts Committee 1937–48

Dr J T INGRAM F R.C P of Leeds chairman of the Leeds Division of the B M.A 1941–44 chairman of the Leeds Joint Council of Industrial Medicine 1942–47 and clinical subdean of Leeds Medical School since 1945

Dr N E WATERFIELD O B E F R.C.S of Little Bookham, Surrey member of the G M.C since 1945 chairman of the central ethical committee of the B.M A 1935–47 and member of council of the Medical Defence Union

INDEPENDENT CANDIDATE

Dr THOMAS BEATON O B F F R C.P of Portsmouth physician-superintendent of St James Hospital and director of mental health services Portsmouth as well as on medicine Very many St Thomas's men will remember his ward rounds, and in a farewell note the *St Thomas's Hospital Gazette* spoke of his untiring industry as a physician and a teacher "Encyclopædic in his knowledge, practical in its application at the bedside, watchful and critical of the newer movements, he was perhaps a trifle cynical with those of lesser clay" He examined for the Universities of Birmingham and London, and for the Conjoint Board

---

[1] London J & A Churchill 1951 Pp 2768 £3 3s

His retirement from St Thomas's in 1926 did not mean retirement from hospital practice, and he continued to act as physician to the Royal Masonic Hospital and to the London Fever Hospital His experience there was expounded in the admirable section on the infectious fevers which he contributed to Price's *Textbook of the Practice of Medicine* He also chose a subject from this specialty—Complications of the Specific Fevers—for the Lumleian lectures which in 1932 he delivered to the Royal College of Physicians He had been elected F R C P in 1906, and he later served the college as councillor He was also a member of the court of assistants of the Society of Apothecaries, and he was an honorary member of the British Pædiatric Association

R C J writes "During the greater part of Box's long career the physician had to form his own diagnosis chiefly on his own clinical observations, and in this Box was a past master He had an uncanny aptitude for recognising what was the matter with his patient But he was a difficult man to know, for he was not a good mixer Though inclined to hold himself aloof he was always ready to help those who went to him for advice All his interest appeared to centre in his work and he allowed himself little in the way of recreation and hobbies" Even in his holidays he showed the same constancy, and year after year he looked forward to his visit to the Channel Islands

In 1905 he married Miss Marian Thyer, of Bridgwater, who survives him

GÖSTA FORSSELL

TRIBUTES were paid to the memory of Gösta Forssell, the Swedish radiologist, at a recent meeting of the Swedish Medical Society[1] The speakers, who included Prof E G E Berven and Prof Aakerlund, recalled how Forssell was working with his first teacher in radiology, Thor Stenbeck, in 1899, when a case of cancer of the skin was for the first time successfully treated with radium To cure this case 150 treatments were given in the course of nine months As Professor Berven points out, a similar case now needs only one treatment, lasting about one minute

[Nordisk Medicin

With his gift for organisation as well as for original research, Forssell changed radiology from a subordinate ancillary service to an independent discipline He insisted that radiology departments, both diagnostic and therapeutic, must have their own organisation, doctors, and nurses, and all the necessary equipment Under his guidance the cramped radiological quarters at the Serafimer Hospital have since 1906 developed into a chain of some 70 radiological departments, with two large central röntgen diagnosis institutes at the Serafimer and Karolinska Hospitals

Radiumhemmet also owes much to Forssell It started in 1910 as a modest hospital with 16 beds, a primitive röntgen apparatus, and 120 mg of radium Today this small experimental venture has become the King Gustaf V Jubilee Hospital at the Karolinska Hospital, with its three departments, Radiumhemmet and the radiophysical and radiopathological research institutes After two years' work at Radiumhemmet Forssell in 1912 presented a report to the Swedish Medical Society on his treatment of inoperable cancer of the uterus with radium, which is now recognised as a classic in the history of radiology He showed that a high proportion of inoperable and advanced cases had improved and in some instances had become symptom free As a result of this paper a national appeal for funds was made, and more than six million Swedish crowns was collected to build and equip the present Jubilee hospital and its institutes

In 1919, Forssell founded *Acta Radiologica*, of which he remained editor till his death, and he was also the founder of the Scandinavian Association for Medical Radiology. In 1925 he attended the first International Radiological Congress in London, and it was a tribute to him, as well as to the standing of Swedish radiology, that the next international congress was held in Stockholm in 1928 Shortly after the first world war he took the initiative in creating a Swedish Association for Medical Research which received an endowment of over 100,000 Swedish crowns on his 65th birthday Last year he was elected an honorary member of the Royal Society of Medicine On the 80th birthday of King Gustaf V, Forssell was chosen to represent the nation in an address to the King—an honour which he probably valued more than any other He died on Nov 13 at the age of 71

Course in Plastic Surgery

A weekend course on the immediate application of plastic principles to the treatment of injury is being held at Rooksdown House, Basingstoke, on June 16 and 17 The course is open only to registrars from the eastern area of the South West Metropolitan Region.

Congress of Anæsthetists

The 26th annual Congress of Anæsthetists will be held in London from Sept 3 to 7, at B M.A House Tavistock Square, W C 1 The manufacturers' exhibition of drugs and apparatus will be at St Pancras Town Hall, N W 1 Copies of the programme may be had from the congress secretary, 25, Park Crescent, W 1

Course on Traumatic Surgery

The institute of accident surgery at the Birmingham Accident Hospital is holding a weekend course on April 20, 21, and 22 Further particulars may be had from the director of postgraduate medical studies, Medical School, University of Birmingham

South African Medical Services

Dr Karl Bremer, the new South African minister of health, speaking at a meeting on March 31, advocated the creation of a central organisation for medical services in the Union At present various local bodies all had their own medical services, which led to overlapping Thus some doctors were employed in hospitals run by the provincial administration, while the government also had their district surgeons, as well as the medical staff they employed at health centres, asylums, and tuberculosis and other hospitals Dr Bremer suggested that the large permanent staff already employed by the State should form the nucleus of a combined State medical service

Awards to Blood-donors

On April 3 the Princess Royal visited the Royal College of Surgeons to present badges to 85 blood-donors, each of whom had given blood at least 50 times The presidents of the three Royal Colleges and the Minister of Health were also present

In a broadcast on April 5 Mr Hilary Marquand, the Minister of Health appealed for 200,000 more volunteers for the Blood Transfusion Service He described his own experience as a recent donor, because, he said, " I thought you'd like to know at first hand that there is no pain, no impairment of activity at all, and that if you re one of those people who happen to dislike the sight of blood you need never see it at all from start to finish All you need do is to send a postcard to the nearest centre and give them your name You'll find the address at your post office, or in the telephone book under Blood Transfusion Service "

London School of Hygiene and Tropical Medicine

In his first annual report as dean of the school, Dr Andrew Topping says that in order to maintain contact with old students an association is to be formed which may be joined by anyone who has followed a recognised course of instruction there ' The large numbers of medical men and women from overseas enrolling for the courses in public health and in tropical medicine make it advisable to continue, and in fact extend, the visits abroad of members of the staff who are able to appreciate what is being done in various countries and to assess their needs " Unfortunately, restrictions have prevented the developments contemplated in 1948 when Winches Farm, St Albans was acquired for the establishment of a field station, " but some work has been done there and it is hoped that in 1951 further funds may become available so that the cramped conditions in the school building may be relieved and the important experimental work which has already been planned may be undertaken "

The report expresses great regret at the resignation of Sir George Elliston from the court of governors and the board of management Appointed to the board in 1943, he succeeded Sir Holburt Waring as chairman in 1944 during the difficult period of the war and the trying years of post war reconstruction, he " served the school with unparalleled devotion and members of the staff who sought his help and advice will never forget his unfailing kindness " His place has been taken by Sir Archibald Gray, F R C.P , and at the annual meeting of the court of governors on March 28, Sir Cosmo Parkinson was elected chairman of the court in succession to Lord Milverton, who has resigned

MIND AND MATTER*

W RUSSELL BRAIN
D.M Oxfd, F.R C P
PHYSICIAN TO THE LONDON HOSPITAL

THE problem of mind and matter has been discussed for over 2000 years, and you may well have come here in a mood of gentle scepticism as to the possibility of hearing anything new upon this topic, but I accepted the invitation to speak about it because it seemed to me timely to review the question in the light of two developments of thought which during the last twenty-five years have contributed to put it in a new light. The first is the great increase in our knowledge of neurophysiology and especially of the electrophysiology of the nervous system. The second is the contribution of those philosophers who are particularly concerned with semantics. I think they often go too far in supposing that problems are purely verbal, but they have rendered a great service by directing our attention to the large part which verbal confusions play in creating difficulties and have thereby clarified our thought. That they have not achieved more is, I think, due to the fact that with the notable exceptions of Eddington (1939), Whitehead (1929), and Russell (1948), to whom, as you will readily detect, I owe much, no modern philosopher seems aware of the importance of the part played by the body in perception and thought, and current philosophies of perception either dispose of such questions as merely verbal or are satisfied with armchair solutions of extreme naïveté.

Before I go further let me add two words of explanation. This is at best a difficult subject, and I believe that if we are to understand even how the difficulties arise we must depart somewhat from the timeworn paths of approach. You must be patient, therefore, if some of the earlier part of this lecture seems to have little relevance to the main problem: its significance will appear later. Secondly, in a broad survey such as I am now attempting there will not be time to discuss every point in detail, to deal with the history of the subject, or to counter opposing arguments. To some extent I can only present conclusions, but I hope to be able to make it clear how they have been reached.

THE PHYSIOLOGICAL CONDITIONS OF SENSATION

Let us begin by considering the use of the words "mind" and "matter". Evidently people think that they mean something when they use the words, and they do not think that they are in the habit of using them for the same events. Going no deeper than the verbal level, if the distinction between the words "mind" and "matter" means anything we should try to understand what it means, and if it does not mean anything we should be clear about that also.

Philosophers and other thinking people who have assumed that there is some distinction between mind and matter have been chiefly concerned with two different questions. (1) What is the relationship between those events we call mental and the collection of matter which we call our brains, and (2) Are the things which we perceive with our senses wholly material or, as some have thought, wholly mental, or partly one and partly the other? As we shall see, these questions are intimately related to one another.

People sometimes put it in this way: "Is the matter *really* mental?" or "Is the mind *really* a manifestation of the matter of which the brain is composed?" Evidently there is something which they mean by matter which, at first sight at any rate, is different from mind, and conversely—whatever these two terms may turn out to represent when we get to know more about them.

Let us, without attempting to define matter, look at some instances of the use of the term. If we ask someone to give us some examples of matter he might say that it consists of solids, liquids, and gases—the earth, water, and air of the earlier philosophers—or that it exists in the form of tables and chairs, muscles and bones, nerves and brains. If we then say "What do you mean by the mind, or what would you regard as mental?" he might find it more difficult to reply. Thought would certainly seem to be mental, for thinking is perhaps the most characteristic function of the mind, as we use the term. Feeling and willing? Yes, those would probably also be regarded as mental. But what about sensation? Is there something mental about colours, touches, and sounds? Here we should begin to get into a difficulty; in fact we should find ourselves at once involved in the ancient controversy between the idealist and the realist. On the one hand if we regard sensations as a state of consciousness we can make out a case for treating them as mental, assuming that the mind is somehow involved in consciousness; but on the other hand the colour of the table certainly seems to be in some way part of the table, though the sound of a bell is not in quite the same way part of the bell and a touch on my hand seems to come into yet another category, because it is not exactly part of the object touching me nor can it be described as part of my hand.

If instead of talking about isolated sensations we think of a solid object which I hold in my hand, what I learn about the object must reach me in the form of touches and pressures, and feelings of heat or cold, together with information derived from the posture of my fingers and the degree of separation of their palmar surfaces from the palm of my hand. Are all these sensations mental or are they part of the object? If I feel that a stone in my hand is cold I do so only because it causes a fall of temperature in my skin which makes my fingers colder than they were and excites certain nerve endings. Yet I usually speak of the stone and not of my hand as being cold, though I can remember a small child putting his hand in the river and saying "I am going to feel my hand in the water".

Let us leave this question on one side for the moment and turn now to what we call the world of matter. How do we know about the tables and chairs, about other people's bodies and brains, and, for that matter, about our own bodies and brains? Let us observe what happens when somebody else, whom we will call A, sees a colour or hears a sound.

The physical stimulus, as we call it, excites the appropriate receptor organ and this in turn starts an electrical impulse in the corresponding afferent nerve. These nerve impulses differ somewhat in minor details, including the rate at which they are conducted towards the central nervous system, but they are substantially alike and no neurophysiologist believes that differences in the nature of the impulses conducted by the afferent nerves correspond to differences in the kind of sensation which they lead us to experience. Thus merely from recording the electrical disturbances which accompany the passage of a nerve impulse and observing their characteristics it is impossible to say whether the sensation with which they are concerned is one of sight, hearing, sound, taste, or touch; and, indeed, it is not until such nerve impulses reach what may be called their end stations, whether these are in the cerebral cortex or the optic thalamus, that we experience a sensation at all. It would seem, therefore, that what determines our awareness of a sensation, and also its nature, is the arrival of a nerve impulse, or more probably a series of nerve impulses at the appropriate end station in the brain.

We have other evidence in support of this view, for clinical neurology teaches us that it is not necessary for the brain to be excited by the arrival of a nerve impulse from the appropriate sensory organ in order that we may experience the corresponding sensation. The same thing will happen if the appropriate area of brain is excited in some other way. Thus we know that if one of the sensory areas of the cortex is stimulated by the electrical discharge which underlies an epileptic fit, or by the physiological disturbance which constitutes an attack of migraine, the patient will experience a sensation; and we know further that a very wide range of sensations, including sight, smell, sound, taste, touch, and others, can all be reproduced by exciting the appropriate area of the cortex, some of them even by the surgeon using an electrical stimulus. It is true that the sensations produced in this way are usually of a somewhat crude kind; but then the stimulus is of a crude kind; and, when once the principle has been accepted that delivery of a stimulus which is capable of evoking a response in the sensory cortex will produce a sensation, there is no reason to doubt that if we were able to deliver a more refined and complicated stimulus, complicated both in its spatial and its temporal organisation, we could produce more complex kinds of sensation.

---

* A British Postgraduate Medical Federation lecture

What follows from this? We have seen that a physical stimulus excites a sensory receptor, and this a nerve impulse; that the nerve impulse, which is in no way like the original physical stimulus, sets going a disturbance in the cerebral cortex which is probably in certain respects unlike the nerve impulse and certainly is quite unlike the original physical stimulus; and that it is upon this cortical disturbance that sensation depends. Hence the cortical state which constitutes the physical basis of a sensation is always quite unlike the physical stimulus which impinges upon the body and which has been in one way or another directly set in motion by the external object which we experience. Thus the relationship between the cortical state which underlies the sensation and the physical object of which that sensation makes us aware is merely that the cortical state is the last of a series of events caused by the physical stimulus. Whatever the relationship between the cortical state underlying a sensation and the corresponding awareness of the sensation in consciousness it would seem to follow that the sensation must be quite unlike the physical stimulus originating in the outside world and exciting the sense organs.

It follows also that the experience of a given sensation must always be later in time than the physical event which initiates it. Indeed it must be later in time than the excitation of the receptors on the surface of the body by that physical event. How much later in time than the physical event it is will depend obviously upon the distance from the body of the object concerned and the rate of propagation of the physical stimulus through the intervening medium. The speed of light is so great that only a fraction of a second intervenes between the time when a light wave is reflected from any object on the earth and the time when it strikes the eye of the observer. This interval is so short that for all practical purposes it can be neglected, and we need pay no attention to it. We behave as though we see something happening at the very moment at which it happens. We cannot do this, however, in the sphere of astronomy where years may pass between the moment at which a light wave leaves a star and that at which the eye perceives it. If it takes several years for the light from a star at which I am now looking to reach my eye, the star can no longer be in the position at which I see it; and, indeed, if it had ceased to exist in the interval between the present moment and that at which the light wave left it I should have no means of discovering the fact. Owing to the relatively slow speed of sound this anomaly may become obvious even on the surface of the earth when sound is concerned. The sound of a jet plane comes from a different point in the sky from that at which we see the plane.

So we reach the idea that the only necessary condition of A's seeing colours, hearing sounds, and experiencing his own body is that the appropriate physiological events shall occur in the appropriate areas of his brain. If these are of the right kind sensory experience will occur irrespective of whether they are caused by a local cerebral disturbance or by a long chain of events originating in the external world. But if we ask A where the events he is experiencing are, where he sees the colours, hears the sounds, or feels part of his body, he does not point to his brain, he points to or describes some region of the external world or some part of his body itself external to his brain.

Here, then is a problem. An event in A's brain causes him to experience something—e.g., see a colour outside his brain. This is what neurologists and psychologists often call "projection," but this is not a very good name for it, for projection seems to imply throwing something from one place to another, but the colour A sees is never anywhere else but where he sees it. He is not aware of any process that could rightly be called projection. The general idea that sensations are in this way as it were manufactured by the brain and somehow or other manage to get outside it into the external world is known as "physiological idealism."

Now let us look at the external world as A perceives it. It is hard or soft, coloured, scented, tasty, composed of objects which have position and move about. As we have seen, the time relationships of A's external world are peculiar. If an event in it causes a sound, he hears it, not when the event occurs, but when the sound, as we say, reaches his ear, or, more precisely, a little later, when the nerve impulse from his ear has travelled as far as the auditory cortex of his brain. Similarly, he sees an object, not when the light wave leaves it, but when the visual nerve impulse has reached his brain, and in the astronomical world this may be a thousand years after the event which originates the light wave.

Consider two stars, one 500 and one 1000 light years away. A sees them both at the same time, but the events he perceives on the stars—i.e., the emission of light waves—happened 500 years apart. So events which A perceives simultaneously are not necessarily simultaneous. In fact A's perceptual view is caused by events stretching away into the past in proportion as they are distant from him in space, and which are on one time scale for vision and another time scale for hearing, in proportion to the differences between the speeds of sound and of light.

What about the body? Surely we have a direct and immediate awareness of that? No, the same principle applies. All A's perception of his body is awareness of its immediate past, for he is not aware of any bodily event until after the interval of time necessary for a nerve impulse to travel from the part of the body in which it occurs to his brain.

THE PERCEPTUAL "WORLD" AND THE PHYSICAL "WORLD"

Hence it would seem that A has to deal with two "worlds"—as we may call them for the moment. There is the "world" of his perceptions and another "world" which differs from the "world" he perceives in various respects, one of the most important of which is that events in this other "world" occur at different times from those at which A perceives them. There is one exception to this—his brain; but here we are dealing with a correlation of a different order, for though it is probably true to say that when an event in A's brain causes a conscious experience the two occurrences are simultaneous, yet in such circumstances A is never aware of an event in his brain but of an event somewhere else. I propose to distinguish these two "worlds" for the moment by calling them A's perceptual "world" and the physical "world." But, you will say, if A's knowledge of any "world" is limited to his perceptions, how does he ever discover that there is any other "world"? He does so by a process of inference operating in two ways.

(i) *He accepts the observations of other people.* Almost the whole of our knowledge of the correlation between sensation and brain function occurs to us in this way. We stimulate the brain and ask the patient for his sensations or we ask about sensations and the effects produced upon them by disease and then study the brain after death. But we can use the sensations of other people in another way—e.g., by using another person as an observer of an event and comparing his observations with our own.

(ii) *He can carry out experimental observations.* In practice he profits by the observations of scientists, but they are of a kind which given the requisite apparatus and skill he could carry out for himself. For example he sees a man hitting something with a hammer. He walks away and notices that he hears each blow at an increasing interval after he sees it occur. From this he infers the speed of sound. Complex physical apparatus enables physicists to infer the speed of light. It follows that from the "world" we perceive we are able to infer a "world" of events of which we are not able to have any more direct knowledge.

Each of us has his own perceptual "world." A's "world" and mine are different both in time and in content. If A stands half way between me and a source of sound he hears the sound at a different time from me; hence his perceptual "world" contains a sound when mine does not, and vice versa. Similarly A's perceptual "world" may contain a phantom limb or a toothache, which I cannot perceive. But if our inferences are made according to the appropriate rules we shall all agree about the physical "world." Thus there is only one physical "world," but as many perceptual "worlds" as there are observers.

At this point let us pause to see how philosophical problems may arise out of verbal confusions in describing the facts of which I have just given an account.

One source of confusion arises from the fact that we do not in everyday life need to distinguish between our own perceptual "world" and the physical "world." When I see a table, I do not need to distinguish a perceptual table from a physical table, nor when I speak of a table do I need to specify whether I am referring to one or the other or both. In fact I pass from one to the other and use the same term for both indifferently.

Now we have seen that A's perceptual "world" and my perceptual "world" are entirely distinct, but that we share the same physical "world," so when A and I talk about a table, all goes well as long as it is not necessary to distinguish between them. But suppose that A suffers from hallucinations and declares that he sees a table when neither I nor anyone else can see one. It is useless to try to persuade A that he is not seeing a table, because his experience is exactly the same as when he has seen a table in the past. In other words there exists a table in A's perceptual "world," but there is no table in the physical "world" in the appropriate situation and therefore there is no table in the perceptual "world" of any normal person. In other words the table in A's perceptual "world" is not caused by a physical table but by something else, and normally a table *in the perceptual "world" is caused by* a physical table.

Hughlings Jackson (1931) makes this point very clearly when he describes a patient who was a cabman and who thought that his bed was a cab. Hughlings Jackson said:

> "This patient saw a cab, had that image strongly 'projected,' his objective state, at a time when I saw a bed, when I had that image strongly 'projected,' my objective state. It is of no avail for trustworthy witnesses to assert that the patient '*could not have seen*' a cab, because there is no cab present, and therefore, that the patient 'only fancied,' &c. that he saw one. Something, not himself, 'got out of' himself the image cab, 'out of' the bystander the image bed. It might be said that this doctrine confuses reality and unreality. But what reality and whose reality? The image cab was the patient's reality; the image bed was the healthy bystander's reality."

The age long controversy between the realist and the idealist in the sphere of perception is greatly simplified if we realise the part which words play in it. If we ask whether the colour of a table is part of the table the answer is "Yes" if by table we mean the table in the perceptual "world" which belongs to each of us, but it is "No" if we mean the table in the physical "world" which is common to all of us. Let us suppose that I see a table, decide that it is in the wrong place, and proceed to move it. It is true to say that in this process I am aware of what are sometimes called sense data—that is to say colours, touches, pressures and so on. It is also true to say that I perceive a physical table. We should normally prefer to say that I moved the table rather than that I moved my sense data, but that is a matter of usage. We have, in fact, two different ways of describing the same events. No difficulty will arise as long as we remember this, but there will be much confusion if we use the two methods indiscriminately.

PERCEPTION AS SYMBOLICAL REPRESENTATION

What, then, is the relationship between them? What is the connection between what I have called a table in my perceptual "world" and a table in the physical "world"? The answer I think is, as I have suggested in more detail elsewhere (Brain 1951), that "if at least what the philosophers call secondary qualities, such as smells, sounds, colours, and so on are quite unlike the physical stimuli which give rise to them, then we must regard them as symbols of physical reality and say that the receptive function of the cerebral cortex is to provide us with a symbolical representation of the external world, not only distinguishing objects by their qualities, but also conveying to us the spatial relationships which exist between them, and at the same time giving us similar symbolical information about our own bodies and their relation to the external world."

Let us apply these ideas to the simple experience of seeing a red light. Making use of conceptual symbols I know that waves of a certain wave length and frequency start at a certain spot and pass through space to my retina, there initiating a series of impulses of quite different frequency which pass along my visual pathways and set up a disturbance in my visual cortex. I then see the red light. The red light in my perceptual "world" is a symbolical representation of the events in the physical "world" of which a certain wave length and frequency are the conceptual symbols; but the events in my cerebral cortex which cause me to see the red light are quite different physically from red light itself. My perceptual "world" therefore is a kind of map. It is not identical with the physical "world" any more than a map is identical with the country which it represents, but it is able to symbolise it because events in my perceptual "world" *stand for* events in the physical "world."

To some people this idea is difficult because our representation of the physical "world" is a three dimensional one, and they find it hard to understand how each of us can have his own three dimensional perceptual "world" which is yet different from the three dimensional physical "world." It may make this idea easier to grasp if we go back to our analogy of the map. It is true that an ordinary map represents in two the brain to be excited by the arrival of a nerve impulse from the appropriate sensory organ in order that we may experience the corresponding sensation The same thing will happen if the appropriate area of brain is excited in some other way Thus we know that if one of the sensory areas of the cortex is stimulated by the *electrical* discharge which underlies an epileptic fit, or by the physiological disturbance which constitutes an attack of migraine, the patient will experience a sensation, and we know further that a very wide range of sensations, including sight, smell, sound, taste, touch, and others, can all be reproduced by exciting the appropriate area of the cortex, some of them even by the surgeon using an electrical stimulus It is true that the sensations produced in this way are usually of a somewhat crude kind, but then the stimulus is of a crude kind, and, when once the principle has been accepted that delivery of a stimulus which is capable of evoking a response in the sensory cortex will produce a sensation, there is no reason to doubt that if we were able to deliver a more refined and complicated stimulus, complicated both in its spatial and its temporal organisation, we could produce *more complex kinds of sensation*

What follows from this ? We have seen that a physical stimulus excites a sensory receptor, and this a nerve impulse, that the nerve impulse, which is in no way like the original physical stimulus, sets going a disturbance in the cerebral cortex which is probably in certain respects unlike the nerve impulse and certainly is quite unlike the original physical stimulus, and that it is upon this cortical disturbance that sensation depends Hence the cortical state which constitutes the physical basis of a sensation is always quite unlike the physical stimulus which impinges upon the body and which has been in one way or another directly set in motion by the external object which we experience Thus the relationship between the cortical state which underlies the sensation and the physical object of which that sensation makes us aware is merely that *the cortical state is the last* of a series of events caused by the physical stimulus Whatever the relationship between the cortical state underlying a sensation and the corresponding awareness of the sensation in consciousness it would seem to follow that the sensation must be quite unlike the physical stimulus originating in the outside world and exciting the sense organs

It follows also that the experience of a given sensation must always be later in time than the physical event which initiates it Indeed it must be later in time than the excitation of the receptors on the surface of the body by that physical event How much later in time than the physical event it is will depend obviously upon the distance from the body of the object concerned and the rate of propagation of the physical stimulus through the intervening medium The speed of light is so great that *only a fraction of a* second intervenes between the time when a light wave is *reflected from* any object on the earth and the time when it strikes the eye of the observer This interval is so short that for all practical purposes it can be neglected, and we need pay no attention to it We behave as though we see something happening at the very moment at which it happens We cannot do this, however, in the sphere of astronomy where years may pass between the moment at which a light wave leaves a star and that at which the eye perceives it If it takes several years for the light from a star at which I am now looking to reach my eye, the star can no longer be in the position at which I see it, and, indeed, if it had ceased to exist in the interval between the present moment and that at which the light wave left it I should have no means of discovering the fact Owing to the relatively slow speed of sound this anomaly may become obvious even on the surface of the earth when sound is concerned The sound *of a jet plane comes* from a different point in the sky from that at which we see the plane

So we reach the idea that the only necessary condition of A's seeing colours, hearing sounds, and experiencing his own body is that *the appropriate physiological events shall occur in the appropriate areas* of his brain If these are of the right kind sensory experience will occur irrespective of whether they are caused by a local cerebral disturbance or by a long chain of events originating in the external world But if we ask A where the events he is experiencing are, where he sees the colours, hears the sounds, or feels part of his body, he does not point to his brain, he points to or describes some region of the external world or some part of his body itself external to his brain

Here, then is a problem An event in A's brain causes him to experience something—e g, see a colour outside his brain This is what neurologists and psychologists often call "projection," but this is not a very good name for it, for projection seems to imply throwing something from one place to another, but the colour A sees *is never anywhere else but where he sees it* He is not aware of any process that could rightly be *called projection* The general idea that sensations are in this way as it were manufactured by the brain and somehow or other manage to get outside it into the external world is known as "physiological idealism"

Now let us look at the external world as A perceives it It is hard or soft, coloured, scented, tasty, composed of objects which have position and move about As we have seen, the time relationships of A's external world are peculiar If an event in it causes a sound, he hears it, not when the event occurs but when the sound, as we say, reaches his ear, or, more precisely, a little later, when the nerve impulse from his ear has travelled as far as the auditory cortex of his brain Similarly, he sees an object, not when *the* light wave leaves it, but when the visual nerve impulse has reached his brain, and in the astronomical world this may be a thousand years after the event which originates the light wave

Consider two stars, one 500 and one 1000 light years away A sees them both at the same time, but the events he perceives on the stars—i e., the emission of light waves—happened 500 years apart So *events* which A perceives simultaneously are not *necessarily* simultaneous In fact A's perceptual view is caused by events stretching away into the past in proportion as they are distant from him in space, and which are on one time scale for vision and another time scale for hearing, in proportion to the differences between the speeds of sound and of light

What about the body ? Surely we have a direct and immediate awareness of that ? No, the same principle applies All A's perception of his body is awareness of its immediate past, for he is not *aware of any* bodily event until after the interval of time necessary *for* a nerve impulse to travel from the part *of* the body in which it occurs to his brain

THE PERCEPTUAL "WORLD" AND THE PHYSICAL "WORLD"

Hence it would seem that A has to deal with two "worlds"—as we may call them for the moment There is the "world" *of* his perceptions and another "world" which differs from the "world" he perceives in various respects, one of the most important of which is that events in this other "world" occur at different *times from those at which* A perceives them There is one exception to this—his brain, but here we are dealing with a correlation of a different order, *for* though it is probably true to say that when an event in A's brain causes a conscious experience *the two occurrences are simultaneous*, yet in such circumstances A is never aware of an event in his brain but of an event somewhere else. I propose to distinguish these two "worlds" for the moment by calling them A's perceptual "world" and the physical 'world." But you will say, if A's knowledge of any "world" is limited to his perceptions, how does he ever discover that there is any other "world"? He does so by a process of inference operating in two ways.

(i) *He accepts the observations of other people.* Almost the whole of our knowledge of the correlation between sensation and brain function occurs to us in this way. We stimulate the brain and ask the patient for his sensations or we ask about sensations and the effects produced upon them by disease and then study the brain after death. But we can use the sensations of other people in another way—e.g., by using another person as an observer of an event and comparing his observations with our own.

(ii) *He can carry out experimental observations.* In practice he profits by the observations of scientists, but they are of a kind which given the requisite apparatus and skill he could carry out for himself. For example he sees a man hitting something with a hammer. He walks away and notices that he hears each blow at an increasing interval after he sees it occur. From this he infers the speed of sound. Complex physical apparatus enables physicists to infer the speed of light. It follows that from the "world" we perceive we are able to infer a 'world" of events of which we are not able to have any more direct knowledge.

Each of us has his own perceptual "world." A's 'world" and mine are different both in time and in content. If A stands half way between me and a source of sound he hears the sound at a different time from me, hence his perceptual "world' contains a sound when mine does not, and vice versa. Similarly A's perceptual "world" may contain a phantom limb or a toothache, which I cannot perceive. But if our inferences are made according to the appropriate rules we shall all agree about the physical 'world." Thus there is only one physical "world," but as many perceptual "worlds" as there are observers.

At this point let us pause to see how philosophical problems may arise out of verbal confusions in describing the facts of which I have just given an account.

One source of confusion arises from the fact that we do not in everyday life need to distinguish between our own perceptual "world" and the physical "world." When I see a table, I do not need to distinguish a perceptual table from a physical table, nor when I speak of a table do I need to specify whether I am referring to one or the other or both. In fact I pass from one to the other and use the same term for both indifferently.

Now we have seen that A's perceptual 'world" and my perceptual "world" are entirely distinct, but that we share the same physical "world," so when A and I talk about a table, all goes well as long as it is not necessary to distinguish between them. But suppose that A suffers from hallucinations and declares that he sees a table when neither I nor anyone else can see one. It is useless to try to persuade A that he is not seeing a table, because his experience is exactly the same as when he has seen a table in the past. In other words there exists a table in A's perceptual "world," but there is no table in the physical "world" in the appropriate situation and therefore there is no table in the perceptual "world" of any normal person. In other words the table in A's perceptual "world" is not caused by a physical table but by something else and normally a table in the perceptual "world" *is* caused by a physical table.

Hughlings Jackson (1931) makes this point very clearly when he describes a patient who was a cabman and who thought that his bed was a cab. Hughlings Jackson said:

> "This patient saw a cab, had that image strongly 'projected,' his objective state, at a time when I saw a bed, when I had that image strongly 'projected,' my objective state. It is of no avail for trustworthy witnesses to assert that the patient '*could not have seen*' a cab, because there is no cab present, and therefore, that the patient 'only fancied,' &c. that he saw one. Something, not himself, 'got out of' himself the image cab, 'out of' the bystander the image bed. It might be said that this doctrine confuses reality and unreality. But what reality and whose reality? The image cab was the patient's reality; the image bed was the healthy bystander's reality."

The age long controversy between the realist and the idealist in the sphere of perception is greatly simplified if we realise the part which words play in it. If we ask whether the colour of a table is part of the table the answer is "Yes" if by table we mean the table in the perceptual "world" which belongs to each of us, but it is "No" if we mean the table in the physical "world" which is common to all of us. Let us suppose that I see a table, decide that it is in the wrong place, and proceed to move it. It is true to say that in this process I am aware of what are sometimes called sense data—that is to say colours, touches, pressures, and so on. It is also true to say that I perceive a physical table. We should normally prefer to say that I moved the table rather than that I moved my sense data, but that is a matter of usage. We have, in fact, two different ways of describing the same events. No difficulty will arise as long as we remember this, but there will be much confusion if we use the two methods indiscriminately.

PERCEPTION AS SYMBOLICAL REPRESENTATION

What, then, is the relationship between them? What is the connection between what I have called a table in my perceptual "world" and a table in the physical "world"? The answer I think is, as I have suggested in more detail elsewhere (Brain 1951), that "if at least what the philosophers call secondary qualities, such as smells, sounds, colours, and so on are quite unlike the physical stimuli which give rise to them, then we must regard them as symbols of physical reality and say that the receptive function of the cerebral cortex is to provide us with a symbolical representation of the external world, not only distinguishing objects by their qualities, but also conveying to us the spatial relationships which exist between them, and at the same time giving us similar symbolical information about our own bodies and their relation to the external world."

Let us apply these ideas to the simple experience of seeing a red light. Making use of conceptual symbols I know that waves of a certain wave length and frequency start at a certain spot and pass through space to my retina, there initiating a series of impulses of quite different frequency which pass along my visual pathways and set up a disturbance in my visual cortex. I then see the red light. The red light in my perceptual 'world" is a symbolical representation of the events in the physical "world" of which a certain wave length and frequency are the conceptual symbols, but the events in my cerebral cortex which cause me to see the red light are quite different physically from red light itself. My perceptual "world" therefore is a kind of map. It is not identical with the physical 'world" any more than a map is identical with the country which it represents, but it is able to symbolise it because events in my perceptual "world" *stand for* events in the physical "world."

To some people this idea is difficult because our representation of the physical "world" is a three-dimensional one, and they find it hard to understand how each of us can have his own three dimensional perceptual "world' which is yet different from the three-dimensional physical 'world." It may make this idea easier to grasp if we go back to our analogy of the map. It is true that an ordinary map represents in two dimensions something which exists in three Nevertheless, a map is really a structure in three dimensions since it must have some degree of thickness and you can easily have a map in which a third dimension is represented arbitrarily but conventionally by lines or colours which stand for the contour But let us extend the analogy Suppose that instead of a map we have a globe Here is a symbolical representation of the whole world in three dimensions with a diameter of a few inches or one or two feet There can be hundreds or thousands of such globes, each of them representing the earth, and there will be plenty of room for them all within the real earth Now, each of our individual perceptual "worlds" possesses a physical basis in the physical "world"—namely, the brain The perceptual "world" depends upon complicated events occurring in the brain and caused by other events in the physical "world" The physical events in each physical brain, therefore, underlie for each of us our three dimensional map of the physical "world" There is plenty of room, in the physical "world" for any number of brains, each of which acts as a basis of one of its representations, just as there is plenty of room in the physical earth for any number of globes each of which acts as one of its models And there is plenty of room for the perceptual "worlds" since, though each of these represents the physical "world" in its entirety, it takes up no more room in it than is occupied by its physical basis in the brain

Now let us pause while I try to sum up and clarify the position we have reached There is only one world which from one point of view consists of physical events including the events in our brain The combination of our sense organs and the nervous system has the peculiar property of creating in various ways symbolical representations of the rest of the world as a result of the impact of physical impulses coming to it from outside itself Each of these symbolical representations is in its totality private to the observer whose consciousness is related to each particular nervous system For the sake of convenience we often speak of this perceptual representation also as "the world" This is as valid as it is to speak of John's photograph as John, but many philosophical confusions have arisen as a result of a failure to distinguish between the world and its representation, because so often it seems natural to use the same term for both

BRAIN AND MIND

We have now reached the crux of our problem concerning mind and matter Experience and our reflections upon it have led us to the distinction between the physical "world" on the one hand and its perceptual representation on the other The physical "world" consists of the subject matter of physics and corresponds in general to what people would loosely term matter Perceptual representation must have a good deal in common with the physical "world"—for example, numerical correspondence—but it also includes much, such as its sensory qualities, which seem to have no counterpart in physics The physical "world" is common to all observers the perceptual representation of it is private and subjective There are also other events which are private and subjective and seem to have much in common with perceptual representation—for example our feelings and our thoughts Again, though these may have an underlying physical basis there is nothing like them in the "world" of physics Many people would apply the term "mind" or "mental" to some at any rate of these subjective events They would probably agree that thinking is mental, and possibly also feeling, but there would be more difficulty in deciding about sensation It seems to me a mere matter of terminology as to how one employs the terms "mind" and "mental" It is, I think, more important to recognise that the one feature which all these subjective states have in common is that they are actually or potentially conscious, and the question we should next consider is what is the relationship between any of these conscious states, such as sensation, feeling, and thought, and their physical basis in the brain Here we seem confronted with two main alternatives We can either take the view that conscious states are not identical with physical brain states They may be parallel with them, or caused by them, the result of interaction between brain states and something else, but they are not the same Alternatively we can take the view that we are dealing with events of only one kind What we call events in the physical brain are happenings about which we may have indirect knowledge inferred from our perception of other people's brains and what they tell us about their experiences, but we have direct awareness of the physical events in our own brains and when we thus perceive them we find them to be thoughts, sensations, feelings, and so on.

Let us consider the arguments for and against these two views The theory that brain events and conscious states are two aspects of the same happenings is sometimes known as "neutral monism" The chief arguments in favour of it are that the correlation between the two is so close that we have no reason to suppose the occurrence of one without the other, and, that being so, it is a simpler and more economical hypothesis to believe that the distinction is created by our mode of thought The arguments for dualism are negative in character There appears to be nothing in the account which physiology gives of the nervous system which can enable us to translate brain events into states of consciousness. As Dr Johnson (1759) put it long ago, "matter can differ from matter only in form, density, bulk, motion and direction of motion to which of these however varied or combined can consciousness be annexed?" Again, Sherrington (1940) writes "The search in that (energy) scheme for a scale of equivalence between energy and mental experience arrives at none The two, for all I can do, remain refractorily apart They seem to me disparate, not mutally convertible, untranslatable the one into the other" Brain-states consist, neurophysiology tells us, of rapidly moving charges of electrical potential in highly complex chemical structures, how can these, however we look at them, ever be identified with sights and sounds, hopes and fears, falling in love, and discussing the nature of the mind?

It is worth while to point out that the difficulty upon which the dualists lay such stress exists for them in just as tough a form For there is no doubt that changes in the physiology of the brain produce parallel and proportionate changes in consciousness It is certainly difficult to see how a pattern of electrical impulses can *be a pain*, but it is equally inexplicable how, if a pain is a state of an independent mind, it can be made much more unpleasant by a lesion of a peripheral nerve or of the optic thalamus, or much less so by prefrontal leucotomy The problem of the influence of nervous structure upon consciousness remains, whether it is supposed to be exerted directly or at one remove upon an intangible mind

In conclusion I want to draw attention to the bearing of certain psychophysiological facts upon this, and then to suggest that it looks somewhat less formidable from the philosophical standpoint I adopted in the earlier part of this lecture I have just mentioned pain Can we imagine how the passage of electrical impulses along certain nerve fibres to the optic thalamus can result in a sensation of pain? There is evidence that it is impossible to stimulate a single pain fibre, so that even from the periphery a relationship between several fibres conducting impulses is involved in the simplest sensation There is also evidence that an alteration in the number of pain fibres, either in the peripheral nerves, or in the pathways in the spinal cord, or in the optic thalamus itself, substantially affects the quality of the pain which is experienced Thus, *it could seem that pain is the state of consciousness which corresponds to a certain pattern of nerve impulses existing in space and time* There is evidence too that patterns play an integral part in our recognition of objects, in our understanding of words and sentences and in our comprehension of ideas Pitts and McCulloch (1947) have attempted to describe in mathematical terms the electrophysiological processes in virtue of which the brain renders possible the recognition of universals

TWO MODES OF KNOWLEDGE

But, you may rightly object, granting all this, granting that patterns of brain activity in space and time play an essential part in making mental processes possible, the gulf between patterns of electrical impulses and the richness and variety of states of consciousness is as wide as ever In the first part of this lecture I drew attention to what I called the *two kinds of* "world," the perceptual "world" and the physical "world," but I said that of course there is really *only one* world Now for the two kinds of world let me substitute two kinds of knowledge of the single world There is knowledge depending upon perceptual symbols, aroused by stimuli reaching the body from outside itself, and which we call perception, and there is knowledge by means of conceptual symbols derived from perception by a process of inference Our knowledge of the physical world *is* of the second kind When therefore we ask how a pattern of electrical impulses in the brain can *be* a colour what we are really saying is "How can events in the physical world for which we use conceptual symbols involving electricity be represented also by the perceptual symbol of colour ?" To be puzzled by this is logically very like asking "How *on earth* can a man called William have a moustache ?" The analogy, I admit, it is not quite perfect, because there *is normally* no connection between being called William and having a moustache, and there is some connection between neurophysiological patterns and colours, but in the present state of our knowledge there is no explainable relationship *between their conceptual* and *perceptual* symbols

THE IMPORTANCE OF STRUCTURE

The view which I have been putting forward has many important and interesting *implications with* which I have not now time to deal It illuminates the difference between externality in the perceptual world and externality in the physical world which is at the bottom of the mystery of so called "projection", but those who are interested in this question will find its psycho physiological aspects discussed by Kohler (1930) and its philosophical aspects by Poincaré (undated) and Russell (1948) It throws light on the presence of somatic data in what we call the external world—see Whitehead (1929) and Sherrington (1940) The idea that objects in the perceptual world contain subjective elements proves to be important *for* the understanding of primitive animism, magic and art But I will confine myself in conclusion to a few brief comments *on the sort of world* we find ourselves in if the ideas I have been discussing are true

First, what is the distinction between *mind and matter ?* This is, more perhaps than we have been accustomed to think, a question of terminology If, following *custom* we describe thought and feeling as mental I see no *reason to* exclude from that term any conscious state, and I would accept the definition of Russell (1948) who said "I hold that whatever we know without inference is mental" It follows that mental experiences are the events in the universe of which we have the most direct knowledge

But, you may ask, if we accept neutral monism and say that the mind and the brain are two aspects of the same thing, is not this merely old fashioned materialism *brought up to date ? But if the stuff of the* universe that we know directly is mind, and matter is the same thing known *only by means of the conceptual symbols* created by mind, it would seem at least as reasonable to call it mind as to call it matter And matter, even crude matter, is not what it was It has turned into energy, and the atom has become a pattern and the molecule a pattern of patterns, till all the different physical substances and their behaviour have come to be regarded as the outcome *of the structure of* their primitive components But we have already met with pattern *in the nervous system,* underlying and rendering possible the most fundamental characteristics of the mind And pattern in some mysterious way possesses a life of its own, for it can survive *a change in the* identity of its component parts as long as its structure remains the same As a wave can move over the sea and remain the same wave, though the water of which it is composed is continuously changing, a pattern can shift over the retina and therefore over the visual cortex and remain recognisably the same pattern The pattern of our personality, though it changes slowly, remains sub stantially the same, though every *protein molecule* in the body, including the nervous system, is changed three times a year (Dodds 1950) The ingredients have altered but not the structure How are we to envisage the physiological patterns upon which mental activity depends ? Pitts and McCulloch have employed complex mathematical formulæ to explain the physiological *basis of abstract* thought, and I do not think that any thing simpler will serve Consider what happens in the visual cortex when *we perceive a circle* As I have said elsewhere (Brain 1946), "we might expect to find that there is something circular about the *events in the cerebral cortex,* for it is these, we are told, which are 'projected' into the outside world when we perceive a circle *Nothing of the sort is true* when we perceive a two dimensional circle we do so by means of an *activity* in the brain which is halved, *reduplicated, transposed,* inverted, distorted and three dimensional." One might add that as no two brains are the same shape, the shape of the physiological disturbance is different in two people looking at the same circle So the comparatively simple process of seeing a circle cannot be explained in terms of the spatial organisation of the corresponding activity in the brain it must, presumably, depend upon the development of complex relationships of these events in space and time which we may find can be expressed only mathematically Once again it is structure, which *is all important* This world surely is very different from the world of the older materialists

One last word Our knowledge, as we have seen, is symbolic our knowledge of the external world is based on perceptions which depend upon the physical structure of the sense organs and nervous system This in itself constitutes a limit to our perceptions, and it is likely enough that it *sets bounds to our* thought also Need we believe that a nervous system evolved to facilitate action upon the physical world is *capable of presenting* the mind with *conceptual* symbols adequate for the whole of reality ? He is a bold man who would claim that today

THE THIGH-NECK CLEARANCE

A SIMPLIFIED RADIOACTIVE TEST OF THYROID FUNCTION

LONDON, AT THE SCHOOL , HONORARY CHEMICAL PATHOLOGIST,
WESTMINSTER HOSPITAL, LONDON

In 1939 Hamilton and Soley first demonstrated the use of radioactive iodine in the investigation of thyroid function Of the techniques since introduced, some are not very suitable for routine use, and others do not clearly distinguish minor variations from the normal The work has been well reviewed by Rawson (1949), Raben and Astwood (1949), Myant et al (1949), Pochin (1950), and Keating et al (1950) The more recent contributions have been concerned mainly with establishing the concept of a thyroid clearance, the theoretical advantages of which are evident from the work of Pochin and his colleagues (Myant et al 1949)

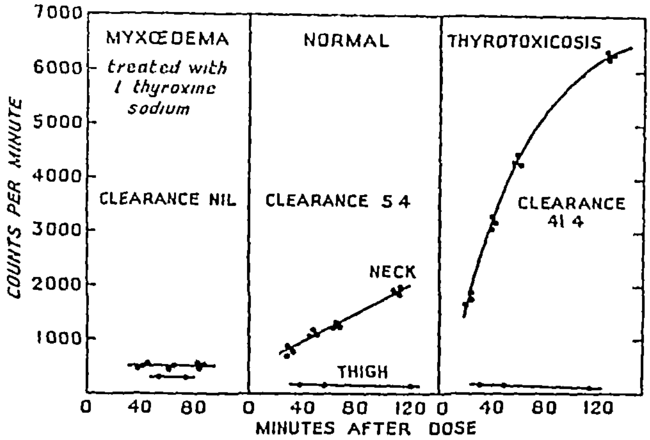

Fig 1—Typical neck and thigh counts after 30 µC of I^{131} by mouth

THIGH NECK CLEARANCE

The plasma iodide clearance as proposed by Myant et al (1949) is not very convenient for routine investigation, because it involves timed venepuncture and the measurement of absolute values of radioactivity, the investigation being spread over two days We have therefore devised a simplified clearance test, which has been reported to the Society for Endocrinology (Foote and Maclagan 1951) As was evident from previous work, changes in thyroid function are well reflected in the neck and thigh counts as shown in the typical results in fig 1 obtained after oral administration of I^{131} It will be seen here that, as one passes from myxœdema through normal to thyrotoxicosis, so the neck uptake curve steepens and the corresponding thigh counts become lower It seemed possible that thyroid function could be estimated by the use of a suitable factor derived from these data, and we have adopted a factor which consists of the rate of uptake in the neck expressed as increase of neck counts per hour, divided by the thigh count, these measurements being made at the time of maximum thigh count This we have called the "thigh neck clearance" The factor is of the nature of a clearance for it relates a rate of increase of thyroid radioactivity to a level of activity in the tissues It must obviously depend on the geometrical conditions of the counting procedure, variations in position of the thyroid gland in the neck, and the relation of thigh to plasma counts, but it seemed to us that these variables might not significantly affect the essential alterations of the factor in abnormal states This hope appears to have been largely realised in practice.

EXPERIMENTAL

Apparatus

The general disposition of the apparatus used is shown in fig 2 The method depends entirely on external γ ray counts over the neck and thigh, and occupies about one and a quarter hours The counts were made with a G 10 lead cathode Geiger Muller tube (20th Century Electronics) of diameter 2·5 cm and effective cathode length 8·5 cm operating at 1100 V and having a shielded background count of 39 counts a minute. This was shielded in a housing of lead, with an effective thickness of 2 cm , except for a rectangular aperture, 11·0 by 5·8 cm , situated in a plane 6 cm from the axis of the counter (fig 3)

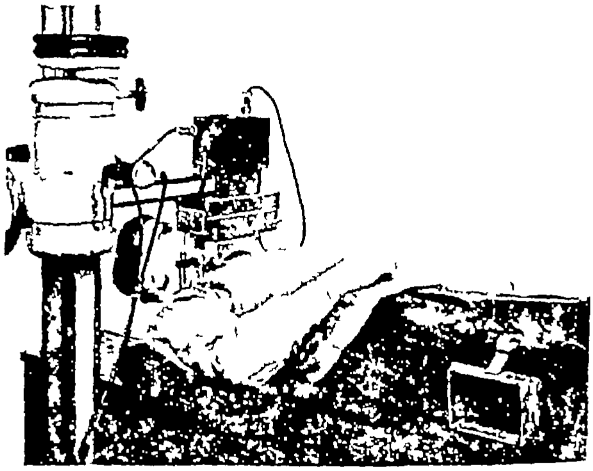

Fig 2—Counting apparatus in use

To avoid heavy lead shielding of the rest of the body, and to enable the patient to lie down, the counter was separated from the neck by a padded aluminium collar (fig 4) so that the axis of the counter lay 11 cm from the

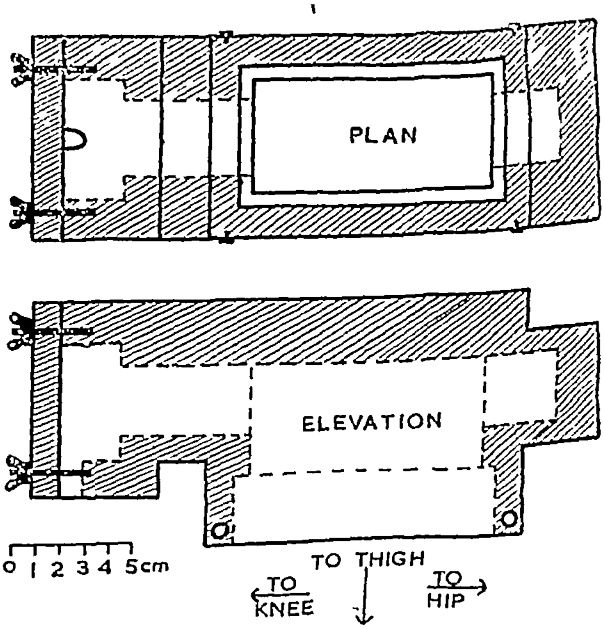

Fig 3—Details of lead counter shielding (made to specification by Stoner and Saunders Ltd. 20, Woodfield Road, W 9)

skin of the neck over the thyroid isthmus. The collar is fixed rigidly to the couch with two adjustable slotted metal supports to which it is attached by hand screws. A similar device was used between the counter and the thigh (fig 2). The anatomical siting over the thigh was standardised by placing the centre of the counter over a point 7·0 cm below the mid-point between the anterior superior iliac spine and the upper border of the patella. To avoid radiation from the opposite thigh a vertical lead block 20 cm square by 2·5 cm, supported on a lead base, was placed between the thighs.

Preparation for Test

For three days before the test the patients studied in this series were not allowed to eat fish, iodised salt, swedes, or turnips, and no drugs or applications containing iodine or goitrogens were given in that period. Although we have no clear evidence to prove that the dietary restrictions were necessary, they seem to be a reasonable precaution on theoretical grounds. Thus, swedes and turnips have been shown to contain goitrogens (see Greer 1950). The omission of iodine-containing medicines or ointments is, however, very important, and neglect of this produced falsely low results in 3 of our cases. The striking effects of goitrogens on iodine uptake are discussed below.

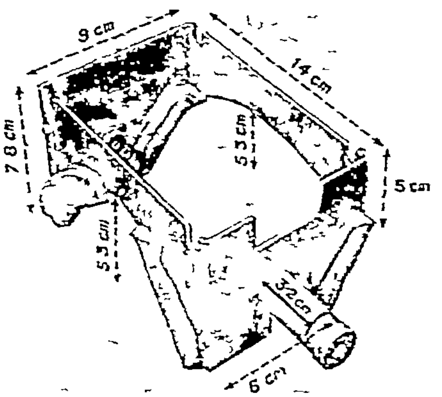

Fig 4—Neck applicator. Thigh applicator is similarly constructed with a depth of 4 cm. at corners and 2·5 cm. at centre of short sides. Sponge-rubber pads 0·6 cm. thick are placed over surfaces in contact with patient.

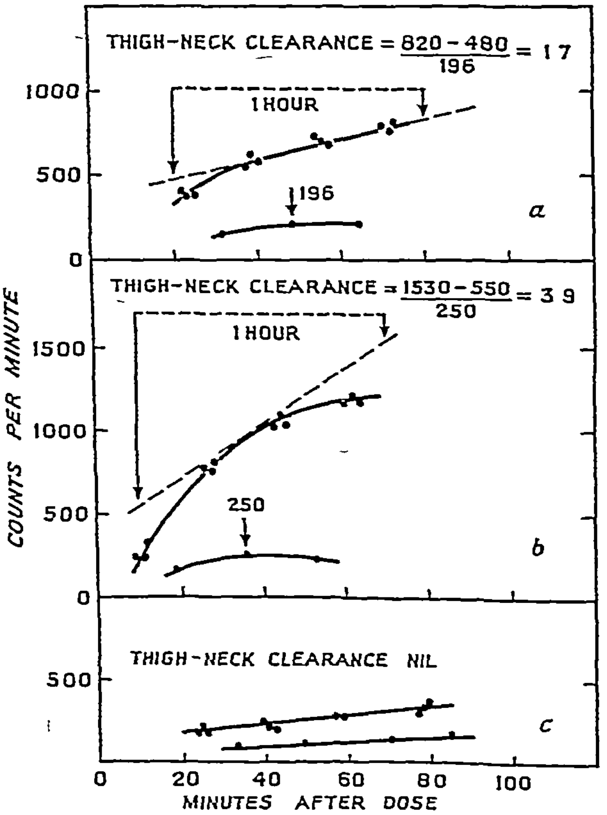
Urine iodine levels were estimated in 70 cases and gave results between less than 1 µg per 100 ml. and 72 µg per 100 ml., calculated as iodine, except for the 3 cases noted above. A qualitative test for urinary iodide is a useful check so far as medicines are concerned and should preferably be done as a routine. This is done as follows: 10–20 ml. of urine is clarified, if necessary, by filtration, and 0·5–1 ml. of 20 vol. hydrogen peroxide is added, followed by 1 ml. of 2N sulphuric acid and 0·5 ml. of 1% starch. Mix well and set aside for five minutes. A blue or smoky colour indicates the presence of iodides in concentration greater than 1 mg (as potassium iodide) per 100 ml. A blank experiment omitting the hydrogen peroxide should be performed.



DETAILS OF TEST

The patient is starved for five hours before the test begins. A dose of about 30 µC of carrier free I^{131} is dispensed in 50 ml. of water with 20 µg of inert potassium iodide added. This is drunk and the time recorded. The glass is rinsed, and the dose washed down, with a few millilitres of water. After ten minutes the patient lies down, and the thigh applicator is fitted and remains in position for the remainder of the test. The neck applicator is fitted and three neck counts lasting ½ minute each are made. The collar is then removed and a ten-minute thigh count is made; these procedures are repeated until the maximum thigh count has been passed. This will have been reached within an hour of counting, unless there is much delay in absorption (a rare event). The data, with background and scaler dead time corrections applied are plotted as a graph, and the calculation, as described above, is made on the best line. Some typical examples of the method of calculation employed are shown in fig 5. A specimen of urine is collected during the test for qualitative iodine tests.

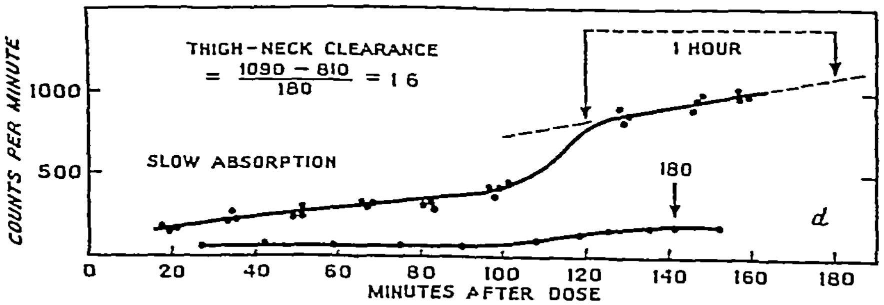


Fig. 5—Method of calculating thigh-neck clearance: *a* in most cases the neck uptake is linear; *b* where the graph of the neck uptake is curved, the tangent is drawn; *c* where the neck thigh ratio is constant for a long time it is not necessary to await the highest thigh count (in a case of Simmonds's disease); *d* occasionally there is delay in absorption from the stomach.

We have standardised the counting distance from the skin over the thyroid at 11 cm. This distance can readily be checked, and with the particular design of collar we have used it is possible to fit all necks so far encountered, except in the shortest and most obese subjects. Variations in the depth of the radiation centre of the gland below the skin surface are more difficult to assess. According to Pochin (personal communication) the radiation centres of thyroid glands lie

2 6 cm below the skin over the thyroid cartilage, with a standard deviation of 1 0 cm It is therefore possible for the distance from radiation centre to counter to vary between 11 5 and 15 5 cm in extreme cases The effect of this on the clearance is discussed below

PLASMA THIGH CORRELATION

To assess the correlation between plasma radioactivity and the corresponding thigh counts we plotted plasma levels against thigh counts in 25 cases two hours after ingestion of the dose, and good correlation was obtained (correlation coefficient =+0 90) In 29 cases a similar graph was prepared for the one hour values and a correlation coefficient of +0 84 was obtained (fig 6) In neither case was it possible to find a correction to the thigh count, based on thigh dimensions, which improved these correlations It is therefore concluded that the importance of thigh dimensions is slight

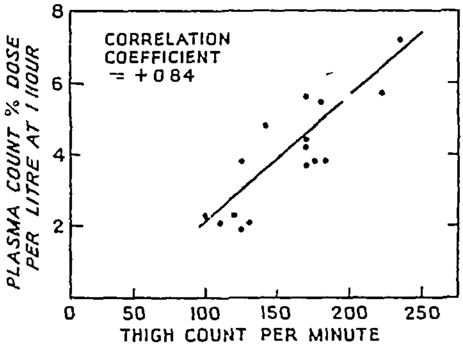

Fig 6—Plasma thigh correlation 1 hr after 30 µC of I^{131} by mouth

It was apparent from a study of the slopes of the regression lines at one and two hours that in this time a considerable diffusion of iodide takes place into the extravascular fluid To assess the effect of diffusion on the relation between the plasma and thigh counts at the time of the clearance estimate, blood and thigh measurements were made on a heparinised volunteer with an indwelling venepuncture needle Fig 7 shows that after initial irregularities during the first forty minutes the thigh count followed the plasma count fairly closely until the maximum values had been reached This is the point at which we calculate the clearance It is not desirable to calculate the clearance before this time, for it is impossible to be certain of the effect of the non-thyroidal tissue count in the neck until the thigh count has shown that this is no longer rising At the moment of the maximum thigh count the slope of the neck curve gives an accurate picture of the rate of uptake of radio iodine by the thyroid gland, and the thigh count gives a good estimate of the plasma level After this time the thigh and plasma counts begin to diverge The critical moment between the effects due to rising plasma count on the one hand and the extravascular diffusion of iodide on the other is thus easily gauged and the clearance calculated without serious risk of error from these causes It may be noted that the maximum thigh count is usually reached before forty minutes in thyrotoxic patients

We have investigated the statistical errors involved in the rather low thigh counts and found that ten minutes is long enough to get a maximal error of 2% in normal persons The lowest thigh count in our series was subject to a maximum error of 7% Since, however, several thigh counts are obtained and the best line is drawn, and since the scatter about this line is always very small, probably such a large error as 7% is rarely met with in practice

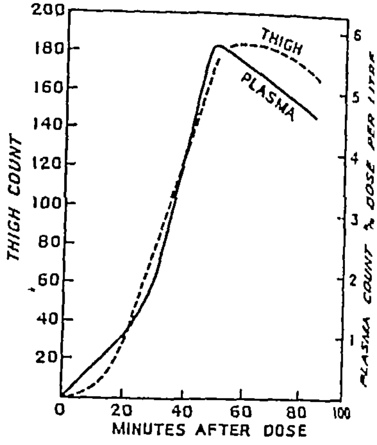

Fig 7—Variation of thigh and plasma count with time after 30 µC of I^{131} by mouth

RESULTS

100 persons have been studied by this technique

24 Normal subjects—Mostly volunteers from the staff of the medical school, with neither history nor signs of thyroid disease and in good health at the time of the test

14 Thyrotoxics—Patients with definite clinical thyrotoxicosis, whether exophthalmic goitre or toxic nodular goitre.

17 Non toxic goitres—Patients with definite goitres but without any signs of toxicity

11 Doubtful toxic goitres—Borderline cases of goitre with equivocal symptoms or signs of toxicity

8 Myxœdemas—5 patients with the fully developed syndrome of myxœdema and 1 of Simmonds s disease with signs of thyroid deficiency (3 of these had been treated with thyroid or thyroxine) and 2 cases of mild hypothyroidism (untreated)

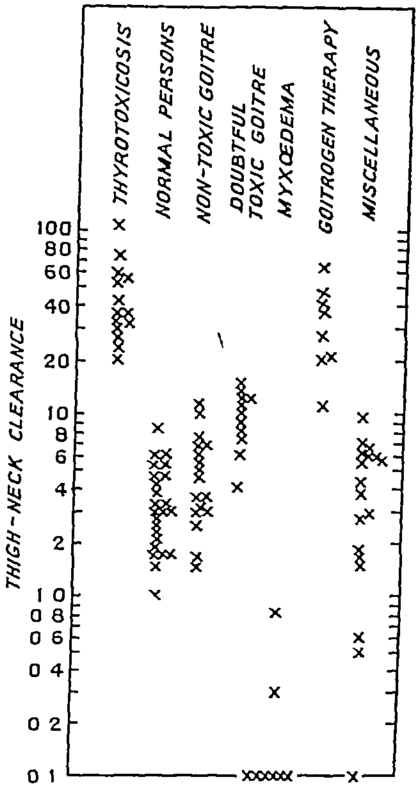

Fig 8—Thigh neck clearance in 100 people. Apparent difference between highest normal clearance (8 6) and lowest thyrotoxic clearance (20 8) is diminished by logarithmic scale used

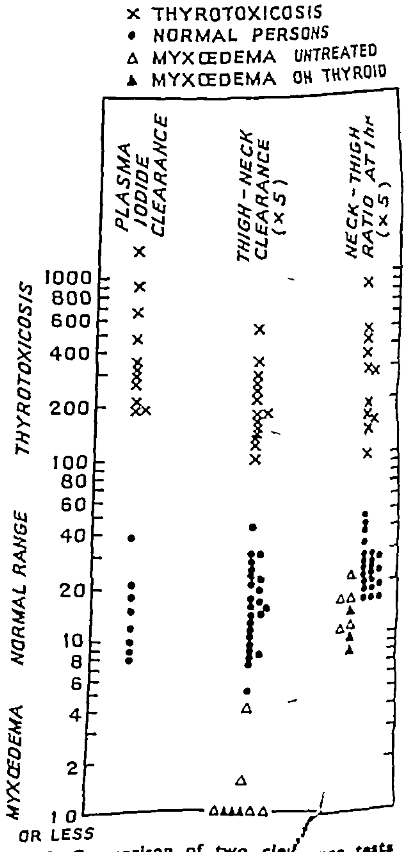

Fig 9—Comparison of two clearance tests and the neck-thigh ratio (Figures for plasma iodide clearance taken from Myant et al (1949))

8 Patients recently treated with goitrogenic drugs (7 with thiouracil, and 1 with resorcinol)

18 Miscellaneous cases —These are further analysed below

The results obtained are given in fig 8 In normal subjects the range was found to lie between 1 and 9 units (mean = 3 5, observed extreme values 1 0 and 8 6) The scatter is such that the logarithms of the values are normally distributed (mean log = 0 49 ± 0 05, standard deviation = 0 23), from which the range (± 2 σ) is shown to be 1 1 to 8 9

Patients with definite clinical thyrotoxicosis gave clearances of 21–108 This illustrates the wide separation from the normal range in this disease

17 cases of non toxic goitre showed a slight extension (2 cases) above the normal range Of 11 cases where the diagnosis of toxicity was in doubt clinically, 5 fell within the normal range and 6 were above normal

In 6 cases of myxœdema (3 untreated) no evidence of thyroid activity could be obtained (clearance less than 0 1), 2 mild cases gave clearances below normal

In 8 patients to whom goitrogenic drugs had been given the results were all above normal, in some cases very high In the 7 patients treated with thiouracil it is difficult to be sure whether the thyrotoxicosis was completely controlled, and in addition there is the possibility of a goitrogen withdrawal effect (Vanderlaan and Vanderlaan 1947), since the drug had usually been omitted for at least three days before the test The latter explanation must be accepted in the one case of resorcinol myxœdema which has been reported elsewhere (Hart and Maclagan 1951)

Miscellaneous Cases —3 results below the normal range illustrated the effect of the ingestion of iodide in the lowering of the clearance 1 case of acromegaly was just above normal 14 normal clearances were found in patients with the following conditions neurosis, Simmonds's disease, exophthalmic ophthalmoplegia with no signs of toxicity, obesity, anorexia nervosa, carcinoma of the thyroid without toxic signs, subtotal thyroidectomy, and oligomenorrhœa with obesity

COMPARISON OF RESULTS

We have compared our results with those of Myant et al (1949) in fig 9 To compare the figures directly it was necessary to multiply our results by 5 to equate the normal ranges, which are then seen to be substantially comparable The clearances in our thyrotoxic patients seem to deviate less from the normal than do those of Myant et al, probably because the mean basal metabolism was lower (+ 39%) in our series than in theirs (+ 63%)—i e, our patients were on the average less toxic On the same diagram can be seen a comparison of our clearance figures with the neck thigh ratios one hour after oral dose Though it is true that, to give the latter test a fair trial, it ought to be carried out after intravenous dosage (Pochin 1950), this result shows the poor differentiation between normal and myxœdematous subjects (with overlap) which is its main disadvantage

DISCUSSION

The aim of the investigations has been to simplify the plasma iodide clearance test, eliminating those factors which make it unsuitable for routine use and yet avoiding any major source of inaccuracy The results obtained seem to confirm the value of the simple thigh neck clearance for diagnostic purposes

Provided that the geometrical conditions outlined above are adhered to, there should be no difficulty in reproducing our results in other laboratories The possible sources of inaccuracy in the test are

(1) Variations in the dimensions of the thighs

(2) The effects of extravascular diffusion of radio iodine into the thigh tissue fluids

(3) Variations of the distance of the counter from the radiation centre of the gland in different cases owing to anatomical variations in the position of the thyroid

The first two factors would affect only the plasma thigh correlation, and the results given above show that this correlation was close It is therefore evident that variations in these two factors are relatively unimportant It seems likely that variations in thigh measurement are to some extent compensatory, for bulkier thighs will have a radiation centre further from the counter The third factor is more difficult to allow for As noted above, the greatest range of distances between the counter and the effective radiation centre of the thyroid with our apparatus lies between 11 5 and 15 5 cm These changes will also be to some extent compensatory, for larger goitres will have radiation centres farther from the counter Variations due to all these causes are of course included in our results and have not prevented a wide separation of the normal from the thyrotoxic and myxœdematous groups

It will be seen from the results that the thigh-neck clearance in thyrotoxicosis deviates from normal about as much as the plasma iodide clearance or the neck-thigh ratio It is, however, much superior to the neck-thigh ratio in the diagnosis of myxœdema The thigh-neck clearance is a rapid and relatively simple procedure, suitable for routine use, and does not require much extra labour compared with the neck thigh ratio We feel that this test is worthy of further clinical trial

All methods of this type are open to the objection that the function of the thyroid gland thus measured—i e, iodine uptake—is not necessarily identical with the more important function of secretion of thyroid hormone The results obtained by most workers up to now suggest that the functions are usually closely correlated, except in the case of patients treated with goitrogens of the thiouracil type, where iodide uptake is high with a low output of thyroid hormone The occasional dissociation between the two functions should, however, be recognised as a theoretical possibility in other conditions

SUMMARY

A new test of thyroid function is proposed, depending on alternate neck and thigh counts after oral administration of 30 µC of I^{131} From these counts a factor is calculated which we have called the thigh neck clearance The procedure occupies about one and a quarter hours.

Data are presented on simultaneous thigh and blood radioactivity estimates which indicate a good correlation between the two at the time when the test is performed

The thigh neck clearance gave readings from 1 to 9 in normal subjects, from 21 to 108 in thyrotoxicosis, from 1 5 to 11 5 in non toxic goitre, from 0 to 0 8 in myxœdema, from 1 5 to 14 2 in miscellaneous diseases including cases of questionable toxicity, and from 11 to 63 in patients undergoing goitrogen therapy

The thigh neck clearance showed changes similar to those shown by the plasma iodide clearance in abnormal thyroid states It is superior to the neck thigh ratio in the diagnosis of myxœdema

We are much indebted to Dr E E Pochin for advice, to the physics department of Westminster Hospital for much technical help, to the Tracer Committee of the Medical Research Council for supplies of I^{131} to the normal subjects who so kindly volunteered for the test, and to the medical and surgical staff of Westminster Hospital for referring cases for investigation

SYNCHRONOUS COMBINED ABDOMINO-VAGINAL HYSTERECTOMY

JOHN HOWKINS
M D , M S Lond , F R C S , F R C O G
ASSISTANT GYNÆCOLOGIST, ST BARTHOLOMEW'S HOSPITAL, LONDON GYNÆCOLOGIST, HAMPSTEAD GENERAL HOSPITAL, ROYAL MASONIC HOSPITAL, LONDON, AND ST JOHN'S HOSPITAL, LEWISHAM

WHEN a surgeon performs Wertheim's operation he aims to remove a generous margin of vagina below the growth—certainly the upper half, and preferably the upper two thirds The amount actually removed is sometimes disappointing and may spoil an otherwise satisfactory operation The reasons for this inadequate removal are either technical—usually obesity or a deep pelvis—or that the growth has infiltrated the vaginal walls in a downward direction In this latter type of case the point of vaginal section is dangerously near the growth, and it is not surprising that recurrence is first noticed in the new vaginal vault Such a recurrence is particularly distressing to the patient in that it tends to ulcerate and bleed and she is reduced to the original state for which she submitted herself to operation

In assessing the site of recurrence Victor Bonney found that in 25% of cases this was in the track of the vagina and the lower pelvis He states that by his abdominal approach he removes all, or practically all, the vagina (Bonney 1947) This is not disputed, but it should be remembered that he has done more than 500 such operations, a total unlikely to be achieved by any future surgeon

The deeper a surgeon descends into the pelvis in an attempt to remove more vagina, the greater his difficulty in hæmostasis and anatomical definition, especially in a fat patient

A conservative and compassionate surgeon will argue that a third or half of a vagina is better than none, and will justifiably point to those cases in which, after Wertheim's operation, the residuum has performed a useful function Be this as it may, the dangerous presence of a potential source of recurrence is a far weightier argument in favour of its primary and total removal

In discussing the possibilities of a vaginal approach Bonney (1947) admits that "the vaginal route may sometimes be chosen (1) in cases of great obesity, especially in multiparæ , (2) in cases in which, in addition to the primary growth in the cervix, a metastatic nodule is present in the lower inch of the vaginal wall" A consideration of these facts can only lead to one conclusion—that in some cases of carcinoma of the cervix both the abdominal and vaginal routes should be used

This principle having been accepted it was put into practice as a two stage operation, the classical Wertheim being followed in a fortnight's time by the vaginal operation from below Two cases were submitted to this procedure without mishap The obvious criticism of the two stage operation is that the patient is twice subjected to the physical and mental trauma of anæsthesia and surgery, and that her stay in hospital is consequently prolonged A second theoretical objection is that the vagina has been transected through a potentially malignant area by the first operation, and that the surgical ideal of wide block dissection of a malignant area beyond the point of possible local metastases has been transgressed

The next logical step was to borrow the technique of Lloyd Davies (1939) as applied to his synchronous combined operation on the rectum, and to employ two surgical teams working from the abdomen and the vagina simultaneously The advantages of this method are evident (1) time is saved , (2) the extent of the operation is widened , and (3) in those parts of the operation which are notoriously difficult when perf either from above or below, the abdominal and v surgeons, when working together, can give each valuable help in finding planes of cleavage safel rapidly and in the identification of anatomical struc A good example is the dissection of the rectum fro vagina When performed from above this may difficult and bloody procedure, but a gynæcologist possibly several thousand posterior colporrhaphi his credit can reach the pouch of Douglas fron perineum safely, quickly, and relatively bloodl The same applies to the separation of the vagina the urethra and bladder

The speed with which the vagina can be diss from the bladder and rectum from below is remark in easy and suitable cases, but it is wise to place more experienced surgeon at the vaginal station the first combined synchronous operation performed Wilfred Shaw and me the vagina was complet separated and freed as far as the cervix by W S bel I, working from above, had tied the uterine arter and the whole operation was completed in forty minutes

PREOPERATIVE TREATMENT

These patients are quite unsuitable for admission nursing homes and the smaller institutions, and shou be transferred to a hospital where the residents a nurses are fully conversant with all the difficulties a complications of major gynæcological surgery Th particularly need an expert pathologist They requ more than ordinary preoperative care, and should l admitted to hospital at least a week before operatio During this period a full and thorough medical examina tion is made, with special reference to the cardiovascula system, and if necessary the opinion of a physician i obtained about their suitability for operation They ar given a high protein diet, special attention being paid to water, salt, and sugar input The blood picture is corrected if faulty, and a blood transfusion is given, so that the hæmoglobin is normal on the day of operation A catheter specimen of urine is collected, and any urinary infection is treated with the requisite drug Special care is taken to obtain an adequate action of the bowels daily without purgation Intravenous pyelo graphy is done in all cases so that a visual picture of renal function and anatomy may be obtained on both sides As soon as possible after admission the patient is examined under an anæsthetic and a biopsy specimen of the growth is obtained The cervix and vagina are best cleaned by frequent douching with dilute hydrogen peroxide or with eusol solution, and between these douches the vagina is packed lightly with acriflavine and paraffin tampons Some patients will need more than a week to build them up to face the operation, and an extra week should never be grudged in these cases It is surprising what a difference such care will make to the ease with which the patient withstands her ordeal I do not myself employ radiotherapy either before or after operation

ANÆSTHESIA

An experienced anæsthetist is essential, and the choice of the anæsthetic is best left entirely to him

My own preference is slightly in favour of extradural block, since this gives excellent relaxation, minimal bleeding, and absence of large and small bowel in the operation area

INTRAVENOUS DRIP

My present practice is to have a slow drip infusion of glucose saline solution running as a precautionary measure in case intravenous blood is suddenly needed The anæsthetist can then give a blood transfusion a once if need be It is better to transfuse too early and too much than too little and too late

TECHNIQUE

As soon as the patient is anæsthetised, the surgeon passes a metal or glass catheter and empties the bladder. It is unwise to entrust this simple duty to an assistant, since a partially emptied bladder, or one with aspirated air in it, is a great embarrassment to the surgeon and always difficult to rectify during the operation. The patient is then placed in the lithotomy Trendelenburg position, employing the special leg rests of Lloyd Davies (1939). A sandbag under the buttocks is unnecessary. The responsible surgeon should satisfy himself that the patient's position is perfect before he scrubs up.

Abdominal Approach

The abdominal team consists of surgeon, assistant surgeon, and theatre sister or nurse, and has its own complete set of abdominal instruments and swabs bearing a distinctive mark, so that there can be no muddle in the count between the two surgical teams. A long subumbilical midline incision is made, and if necessary this is carried through the umbilicus high enough to give a generous field of operation. After the abdomen has been opened, the ureter is brought into view, the ovario pelvic fold is clamped at its highest possible point, and the round ligament is clamped as far laterally as possible. The peritoneum between these two points is incised, and its mesial leaf is mobilised towards the midline with the ureter. In this way the ureter is identified straight away and followed from above downwards at the very beginning of the operation. The pons asinorum is thus crossed early. The technique of Bonney's classical Wertheim's operation has been followed up to this point, but now comes a modification. The external iliac and obturator glands, plus fat and connective tissue, are swept medially, so that a block dissection of the growth and its glands is made from above downwards and centripetally. This manœuvre enables the uterine artery to be tied in its most proximal part and if necessary the internal iliac artery can be tied at its source. The operation is continued as described by Bonney (1947).

Vaginal Approach

The vaginal operator, meantime with his assistant, his theatre sister, and his own instruments and swabs, makes a circular incision round the vagina in the region of the hymen. This manœuvre is assisted by sewing the labia minora to the skin. A bladder sound can be passed if necessary. The anterior vaginal wall is dissected from the urethra, and the posterior vaginal wall from the perineal body and rectum. When an inch or so has been freed all round, the vagina is lightly but firmly packed with gauze soaked in Bonney's blue and then sewn up with multiple interrupted silk sutures which are left long, and to which is attached a pair of Spencer Wells forceps to act as a tractor. The dissection then proceeds in front, behind, and laterally. In front the bladder is soon reached and stripped from the vagina by sharp and blunt dissection as far up as the cervix. The ease of this dissection depends on the position of the growth, and it is more difficult where the vagina is involved. Posteriorly the rectovaginal space is soon reached as in the operation for posterior colpoperineorrhaphy, and the peritoneum of the pouch of Douglas comes into view. Laterally the puborectalis muscle is inserted through a broad fan like muscular base into the vagina, and this has to be cut with scissors. Certain vessels may require to be tied, and hæmorrhage in this part of the operation is liable to be brisk; hence in some cases it is wiser to proceed by clamp and suture ligature. Quite soon, however, the operator will find his finger above the levator ani muscle and just below the cardinal ligaments. He should now pause and assure himself that all bleeding vessels are secured, and if there is heavy venous oozing, it is best to plug tightly for a few moments until the hæmorrhage abates and individual vessels can be comfortably and safely secured. Diathermy is sometimes useful in such a situation and should always be available. Having reached this point of the vaginal operation, the vaginal and abdominal surgeons should now review the position, and it will usually be found that a common plane of cleavage can be established in the midline, so that the fingers of the two surgeons can meet between the bladder in front and the vagina and cervix behind. The abdominal surgeon will by now have dissected the ureter out of the ureteric canal, and Mackenrodt's ligament can be secured as far out laterally as possible, both from above and below, and cut and tied while the ureter is identified and guarded by the abdominal surgeon. When this has been done on both sides, the two surgeons turn their attention to the peritoneum covering the posterior aspect of Douglas's pouch, which is now incised from above, while the vaginal operator guards the rectum and presses it back with his fingers from below. The uterosacral ligaments are divided by the abdominal operator well back, the rectum being still guarded by the vaginal operator.

In dividing the uterosacral ligaments it is important not to divide them so near the sacrum as to endanger the terminal branches of the superior hæmorrhoidal artery which encircle the rectum in a descending spiral. These vessels are particularly important, because the anastomosis with the middle hæmorrhoidal artery may be poor. Moreover, the middle hæmorrhoidal artery may have been interrupted by the dissection. Damage to the superior hæmorrhoidal artery can therefore cause avascular necrosis of the rectum, with the formation of a fistula. The risk of this type of fistula has been pointed out by Von Peham and Amreich (1934). It is therefore wise not to take the uterosacral dissection farther back than the anterolateral aspect of the rectum.

The vaginal surgeon has now completed his task, and his remaining duty is to deliver the specimen from the vagina, if the uterus is not too big—e.g., when fibroids are present. Having done this he makes a final inspection for the sake of absolute hæmostasis and lightly packs the cavity with flavine and paraffin gauze. Sometimes one or two catgut sutures are passed in front of the rectum through the levatores ani. While he is doing this, the abdominal surgeon completes the peritoneal suture across the floor of the new pelvis. The vaginal surgeon passes and leaves in situ a self retaining catheter, the efflux from which should show a few drops of clear urine. Some surgeons like to dust the cavity from which the vagina has been removed with sulphonamide and penicillin powder and to do the same to the peritoneal floor from above. The abdomen is closed without drainage.

POSTOPERATIVE CARE

The combined operation is a formidable procedure, and even if shock is not present at the time of operation it is liable to come on later. This delayed type of shock is a particular menace in Wertheim's operation, and the surgeon should take precautionary measures against it.

When the patient has returned to the ward she is given morphine gr. 1/4 at intervals of 4–6 hours for the first 24–48 hours and treated along the accepted lines for any major abdominal operation. The surgeon should look out particularly for ileus and peritonitis, because pelvic infection is liable to follow any opening of the vagina, even in a total hysterectomy. For this reason postoperative prophylactic chemotherapy is advised.

The intravenous drip should not be discontinued until the pulse chart fully warrants it and until the oral fluid intake and the activity of the gut are both satisfactory. The vaginal packing is removed with the help of morphine gr $^1/_4$ at the end of 48 hours, and there after the cavity is lightly packed daily or every second day with acriflavine and paraffin soaked gauze for the next few days The sooner this packing is discontinued the better Some serosanguinous fluid and, later, some seropurulent discharge will be lost from the cavity, and secondary hæmorrhage requiring repacking, though not serious, has been encountered once Although after other operations I encourage my patients to get up as early as possible, after this operation it is probably best to confine the patient's out of-bed activities, for the first 10 days, to sitting in a chair, but no hard and fast rule should be laid down

The treatment of the bowels follows ordinary practice, but only simple rectal washouts are used if there is any distension The bladder will need careful supervision in that, after the removal of the catheter about the 5th day, the patient is always liable to have some residual urine, the presence of which must be ascertained by trial catheterisation after she has emptied her bladder in the ordinary way Residual urine, if present, needs no specific treatment and usually clears spontaneously in about 3 weeks The vaginal cavity may not entirely heal for several weeks, but this need cause no anxiety and can be treated at home by frequent baths and a simple vulval dressing

POSTOPERATIVE COMPLICATIONS

Hæmorrhage—If operative technique is satisfactory and hæmostasis thorough, secondary hæmorrhage should not be a serious complication Oozing from the vaginal bed is largely controlled during the first 48 hours by the vaginal pack, and if anxiety is experienced repacking with or without anæsthetic will dispose of this trouble

Shock—This severe and radical operation is naturally liable to shock the patient, and for this reason blood transfusion should be generously used and oxygen given through B L B mask

Postoperative Retention of Residual Urine and Urinary Infection—The motor nerve supply to the bladder is bound to be damaged if the operation is thorough, and resulting retention of residual urine is to be expected This complication will need initially an indwelling catheter and continuous drainage, and subsequently catheterisation two or three times a day until the bladder regains its tone This usually takes three weeks, but may take longer Recovery is always eventually complete, hence no undue anxiety need be felt Urinary infection is to be expected, and this can be treated by prophylactic chemotherapy as and when it arises

Damage to Bladder and Ureters—In all radical operations for carcinoma of the cervix the bladder and ureters are in peril, especially with the more advanced growths The surgeon should not strip the ureter too thoroughly in its lower reaches, and certainly not for more than two inches, otherwise the danger of avascular necrosis is increased

Damage to Rectum—In the synchronous combined operation the rectum is less in peril than in the classical Wertheim, because the vaginal operator can more easily recognise the pelvic anatomy from below, and Douglas's pouch is opened by both surgeons The question of damage to the superior hæmorrhoidal arteries when the uterosacral ligaments are divided posteriorly has already been mentioned, and its importance in the causation of fistula has been emphasised Such a fistula appears between the 7th and the 14th postoperative days If the rectum is damaged at the operation it should be carefully repaired and a temporary colostomy made

Phlebothrombosis and Pulmonary Embolism—In a few cases of Wertheim's hysterectomy I have tied the common iliac vein on both sides, but I do not yet advise this as a routine, since the results of heparin treatment have been satisfactory

Postoperative Vomiting and Paralytic Ileus—The intravenous drip used for blood transfusion should be kept running with 1/5 physiological saline solution and 4% glucose until the gastro intestinal tract resumes its normal functions Early use should be made of continuous duodenal and jejunal suction if the patient vomits or becomes distended

Peritonitis should be prevented by postoperative chemotherapy, for soiling of the peritoneum is to be expected from the vagina

Slow Obliteration of Vaginal Cavity—This may take six months, but does not require hospital treatment other than frequent supervision in the outpatient department Patients are instructed to take two baths a day, and probably the best results are obtained without any other local treatment Any discharge is absorbed on a sterile vulval pad, changed frequently

SUMMARY AND CONCLUSIONS

Synchronous combined abdomino vaginal excision of the uterus and vagina is described It is a more radical and thorough procedure than the classical Wertheim's operation, and removes a potential site of recurrence—i e, the vaginal residuum This should improve the estimated cure rate obtained by surgery It is particularly suitable for cases where the growth has spread into the vagina

The operation is not technically difficult, and it should be performed as quickly as the classical Wertheim's operation

The bladder and ureters are less likely to be damaged than in the classical Wertheim, since in the difficult part of the operation the two surgeons can assist one another

It is not suggested that the operation should supersede the classical procedure, but that in some cases it will render difficult growths more easily operable.

I wish to acknowledge the valuable help and criticism I have received from my old chief, Mr Victor Bonney, and my senior colleague Mr Wilfred Shaw, also the collaboration of Mr Emlyn Williams, Mr J J O'Sullivan, and Mr S F Hans

DETERMINATION OF HÆMOGLOBIN

VII STANDARDISED OPTICAL DATA FOR ABSOLUTE ESTIMATIONS

R Donaldson R B Sisson

R G Macfarlane
Radcliffe Infirmary, Oxford

A UNIVERSALLY available standard to facilitate absolute determinations of hæmoglobin is becoming more than ever necessary with the increase in inter comparison of results for nutritional surveys and other research work Since the final stage of most estimations involves a comparison of optical absorptions or colours, it is desirable that a common optical standard should be available

The absolute accuracy of a result obtained by an optical method depends on two distinct factors (1) the precision or reliability of the estimate, and (2) the accuracy of the relationship between the optical values and the true hæmoglobin content of the blood sample e precision takes account of the random errors asso-ted with the preparation of the solution and its easurement, this has been dealt with in papers III d v of this series Paper IV gave details of the prob ns connected with the determination of hæmoglobin iron analysis, which is regarded as the method that ost nearly gives the total hæmoglobin content Paper II ve a definition of the existing B S Haldane standard terms of hæmoglobin content To complete the formation necessary for accurate determinations, the lationship between optical values and hæmoglobin ust be known This paper gives those optical equivalents at will enable most instruments to be calibrated curately in terms of the agreed hæmoglobin standard

PRINCIPLES OF OPTICAL STANDARDISATION

Optical estimations involve a comparison of colours r absorptions against some kind of optical standard t may be a coloured liquid or glass, as in the Haldane, lkaline hæmatin, and Sahli methods, it may be simply scale of light intensities, as given by a photocell and alvanometer, or for null instruments it may be a ariable diaphragm calibrated in densities, or a neutral edge, which in the M R C photometer is calibrated irectly in % Haldane

When an instrument is used with a material standard he necessity for absolute accuracy of the optical scale s removed, but the results obtained still depend on the ccuracy with which the material standard has been efined Since its optical calibration in terms of hæmoglobin is in itself a very lengthy and difficult procedure, he use of a material standard is often of doubtful alue and can lead to significant systematic errors which re only revealed when intercomparisons are made

The alternative is an absolute optical standard of ensity This can be satisfactorily established only by a large scale experiment, such as that described below, where the most modern and reliable methods and equipment have been used to determine optical values and hæmoglobin content by iron analysis The fundamental results for optical standardisation are the spectral absorption curves of the various derivatives These results are, of course, only directly applicable to instruments which use monochromatic light, spectroscopes, or absorptiometers with a line source and isolating filter The large majority of hæmoglobinometers, however, use either a simple colour match or a brightness estimation through a so called monochromatic filter In the latter case, instead of monochromatic light, a band of wave lengths is involved, the components of which are absorbed at different rates However, it is possible to calculate absorption values appropriate to any filter from the fundamental spectrophotometric curves This calculation gives a completely rigorous result and does not just assume that the filtered light behaves as monochromatic corresponding to the peak transmission of the filter Results have been worked out for the commercial green filters generally used in visual and photo electric hæmoglobinometers

With this information, the subsequent calibration of simple hæmoglobinometers is straightforward The improvement of optical apparatus, especially photocells and robust galvanometers, has made possible the production of absorptiometers which can be made to measure optical density with sufficient accuracy Such an instrument can be used to give hæmoglobin values independent of any material standards

PROCEDURE

Iron analyses were made on normal blood samples from 11 males and 10 females Six derivatives from each blood were prepared, and spectrophotometric curves were obtained for each derivative In addition the colour of the carboxyhæmoglobin solution was estimated as a percentage of the B S Haldane standard

Optical data, applicable to various types of hæmoglobinometers, were then derived from the spectrophotometric results

METHODS

Sampling and Iron Analysis —The blood samples were taken and iron analyses were made as described by King et al (1948a)

Hæmoglobin Derivatives —The six derivatives and the method of preparation are described by Macfarlane et al (1948)

Colour and Absorption Measurements —These were made on the N P L colour comparator and spectrophotometer, both of which are described by King et al (1948a)

RESULTS

Spectral Absorption

Absorptions at every 10 mμ throughout the visible spectrum were determined for all six derivatives from each blood sample The absorption peaks were not explored in detail, since all the information necessary for the standardisation of hæmoglobinometers can be obtained from the 10 mμ curves The measured values, being the absorptions of the solution in a 1 cm cell compared with that of water in a similar cell, were reduced to specific extinction coefficients $\left(E^{1\%}_{1\text{cm.}}\right)$ corresponding to a standard concentration of 1 g of Hb per 100 ml. The 21 values of $E^{1\%}_{1\text{cm.}}$ at each wave length, were averaged, and a mean curve was obtained for each of the six derivatives (table I and figs 1 and 2)

These results may be used directly in the measurement of hæmoglobin with a spectrophotometer, providing care is taken to adjust the slits to the correct spectral band-width

Hæmoglobinometers using Monochromatic Light

For instruments which use the mercury green or sodium yellow lines the appropriate absorptions, interpolated from the values in table I, are given in table II

TABLE I—SPECTRAL ABSORPTION, MEAN CURVE, 11 MALES, 10 FEMALES

Wave length (mμ)	Optical density of solution containing 1 g of Hb per 100 ml $\left(E^{1\%}_{1\text{cm.}}\right)$					
	Oxy hæmo globin	Carboxy hæmo globin	Acid hæma tin	Alkaline hæma tin	Cyan hæma tin	Cyan met hæmo globin
430	33 0	35 0	21 2	14 7	39 0	40 0
440	16 1	11 1	19 4	11 1	21 2	20 7
450	9 59	6 42	17 2	8 91	14 2	13 2
460	6 66	4 81	14 2	7 48	10 1	8 83
470	5 05	4 02	11 6	6 53	7 72	6 51
480	4 12	3 60	9 37	5 80	6 39	5 60
490	3 58	3 40	7 94	5 26	5 38	4 84
500	3 26	3 36	7 26	4 77	4 66	4 34
510	3 12	3 74	7 05	4 34	4 65	4 45
520	3 79	5 10	7 02	3 99	5 30	5 26
530	6 41	7 50	6 83	3 80	6 16	6 20
540	8 58	8 61	6 40	3 57	6 47	6 46
550	6 92	7 14	6 13	3 40	6 35	6 25
560	5 16	7 25	5 86	3 34	5 64	5 51
570	7 10	8 57	5 15	3 33	4 74	4 63
580	8 00	4 89	4 03	3 32	3 73	3 63
590	2 25	1 73	3 26	3 28	2 77	2 64
600	0 72	0 80	2 93	3 20	1 90	1 77
610	0 46	0 56	2 73	3 04	1 30	1 16
620	0 35	0 41	2 53	2 72	0 94	0 82
630	0 29	0 32	2 53	2 26	0 74	0 63
640	0 25	0 27	2 72	1 74	0 61	0 50
650	0 21	0 22	3 07	1 26	0 57	0 39
660	0 18	0 18	3 25	0 98	0 53	0 33
670	0 17	0 16	2 99	0 77	0 49	0 29
680	0 16	0 15	2 26	0 64	0 46	0 26
690	0 15	0 15	1 49	0 56	0 43	0 23
700	0 15	0 15	1 0[illegible]	0 51	0 40	0 21

These values can easily be transformed to apply to solutions of any required concentration from blood of any strength—e g at 560 mμ, E for oxyhæmoglobin is 5 16 for a 1 in 200 dilution from blood containing 14 8 g of Hb per 100 ml the equivalent value at 560 mμ is 5 16 × 14 8/200 = 0 382

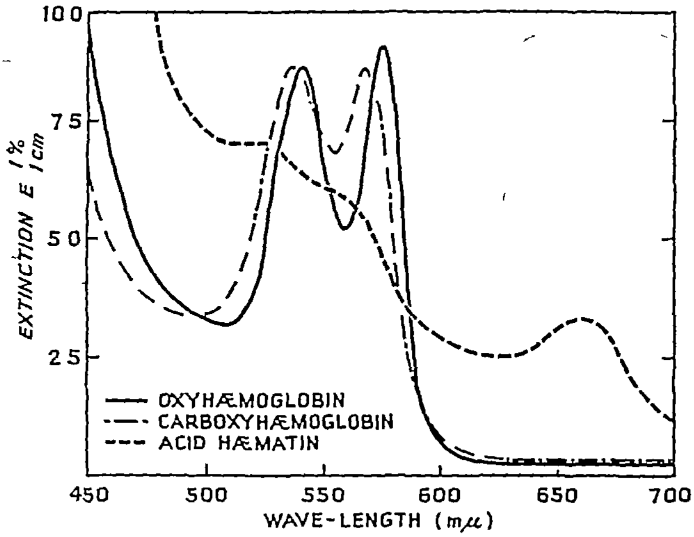

Fig 1—Absorption curves of hæmoglobin derivatives

Here, as in table I, the results are in terms of $E^{1\%}_{1cm}$ but can be transformed to apply to any required concentration

Hæmoglobinometers using a Colour Match

When a hæmoglobinometer operates on a straightforward colour match, the natural optical standard is the trichromatic specification of colour This was the method adopted in the original Haldane specification (Donaldson et al 1943) The only other hæmoglobin derivative which is widely used in colour matching is acid hæmatin, for which a yellow glass is often used as a standard The trichromatic colour specification is essential for an optical calibration of this kind of hæmoglobinometer, because the glass has a different spectral absorption from that of acid hæmatin, although it matches it in colour Only the trichromatic method can show how closely a given glass matches acid hæmatin, the value on the hæmoglobin scale, and whether the match changes seriously on going from daylight to artificial light Details of the trichromatic methods are now available in textbooks, e g, Wright (1944) The colour values of carboxyhæmoglobin and acid hæmatin measured not less than 2 hours after making up are given in table III

Hæmoglobinometers using Monochromatic Filters

A series of results applicable to visual and photo electric hæmoglobinometers using monochromatic filters have been derived from the spectral absorption data of table I and are mathematically consistent with it

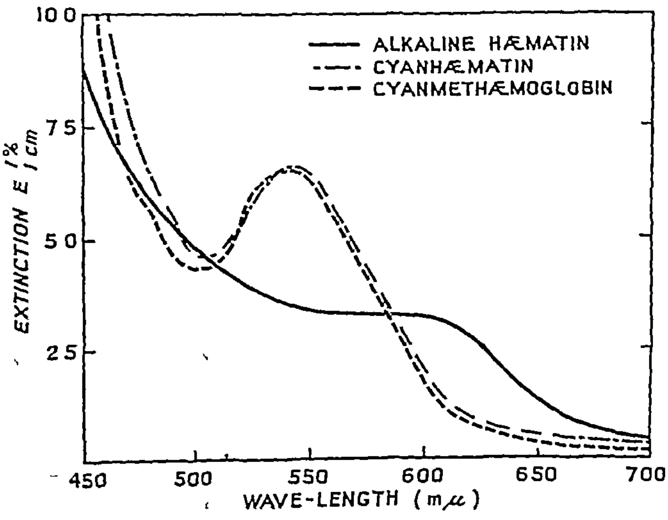

Fig 2—Absorption curves of hæmoglobin derivatives.

The spectral transmissions of the filters were obtained by measurement of a representative selection from the current commercial production The spectral curves are shown in figs 3 and 4

Visual Instruments

To get results which apply to a visual instrument one requires, in addition to the properties of the filter and hæmoglobin derivative, the photometric luminosity curve for the eye and the spectral energy of the illuminant It has been assumed that visual instruments are used mostly in daylight, so the illuminant chosen was the colorimetric illuminant B which is equivalent to sunlight

The optical density has been calculated of each hæmoglobin derivative for a visual instrument using brightness matching in filtered light In effect each filter is treated as a band of wave lengths, the result for each wavelength is calculated, and the final result is derived by integration The mathematical processes involved are given in the appendix The results for all seven filters are shown in table IV

Photo electric Instruments

To get similar results applicable to a photo electric instrument the spectral response of the photocell is *substituted for the luminosity response of the eye* An average response curve was chosen as representative of the selenium barrier layer photocells manufactured commercially in this country The average curve should suit all cells because it is only variations within the waveband of the filters that are significant Photo electric instruments are usually fitted with a tungsten lamp, so the spectral energy of a gas filled projector lamp was taken to represent the illuminant

TABLE II—ABSORPTION FOR MERCURY GREEN AND SODIUM YELLOW LINES, MEAN VALUES, 11 MALES, 10 FEMALES

Wave length (mμ)	Optical density of solution containing 1 g of Hb per 100 ml ($E^{1\%}_{1\,cm.}$)					
	Oxy hæmo globin	Carboxy hæmo globin	Acid hæmatin	Alkaline hæmatin	Cyan hæmatin	Cyan met hæmo globin
546 (Mercury green)	8 10	7 70	6 21	3 45	6 43	6 38
589 (Sodium yellow)	2 64	1 82	3 30	3 29	2 84	2 70

The optical density of each derivative for a photo electric *instrument, and variations from* Beer's law, have been calculated The results are shown in table IV

Filter Transmissions

Table IV deals with the transmissions of the hæmoglobin derivatives for light which has been filtered by passage through any of the seven filters, but no account *is taken of the amount of light* transmitted by the filters. Now, although the transmission of any one derivative does not vary by more than 2 to 1 in going from one filter to another, the transmissions of the filters vary over a 20 to 1 range This means that, for any given source, the amount of light reaching the eye or the photocell can vary over this 20 to 1 range, according to which filter is used Other factors *being equal, it is obviously* desirable to choose the filter which has the highest transmission, since in most instruments an increase in the light available tends towards an increase in precision of measurement

In table V the columns headed "Vis" give for each derivative the values for the percentage of light transmitted by the solution plus each of the filters when used

TABLE III—COLOUR COÖRDINATION OF CARBOXYHÆMOGLOBIN AND ACID HÆMATIN, MEAN VALUES, 11 MALES, 10 FEMALES

(1 in 100 dilution from blood of concentration 100% Haldane —i.e., 14·8 g of Hb per 100 ml)

Hæmoglobin derivative	Colour coördinates		
	x	y	z
Carboxyhæmoglobin (7·14 mm *)	0·4824	0·3457	0·1719
(B.S.I. Haldane standard)	(0·4805	0·3432	0·1763)
Acid hæmatin (7·14 mm)	0·5148	0·4306	0·0546

* Internal diameter of Haldane test tube

The difference in the trichromatic coefficients of the two carboxyhæmoglobin solutions indicates not a difference in strength on the Haldane scale but merely a slight brownness of the present solutions This brownness is probably the result of differences in the methods of making up the solutions. The Haldane standard solution was allowed to stand for some weeks and was then decanted to ensure that a minimum of insoluble matter was present in the measured solution in the present work the solutions to be measured were made up immediately from the whole blood

in visual instruments, the illuminant, as before, is the standard illuminant B In the columns headed "P.E" are tabulated comparable results for photo-electric instruments, the illuminant is a tungsten filament lamp

PRACTICAL TEST OF RESULTS

King et al. (1948b) in paper VI described observations on a later series of blood samples which showed that two M.R.C photometers gave values on an average less than 0·5% different from those obtained by iron analysis These instruments had been calibrated by purely optical methods based on the values in table IV

In the course of this experiment estimations were also made on all six derivatives with a photo electric absorptiometer calibrated in a similar way for use with an Ilford 625 filter The strengths of each of the ten blood samples were estimated by iron analysis, by the absorptiometer, and by the most reliable of all optical methods, the colour derived from spectrophotometric curves The absorption results were expressed as percentages of the 100% value given in table IV the results by iron analysis as percentages of 14·8, and the optical values were then divided by the results by iron analysis and expressed as percentages The mean and standard deviation of all ten quotients for each derivative and method are given in table VI.

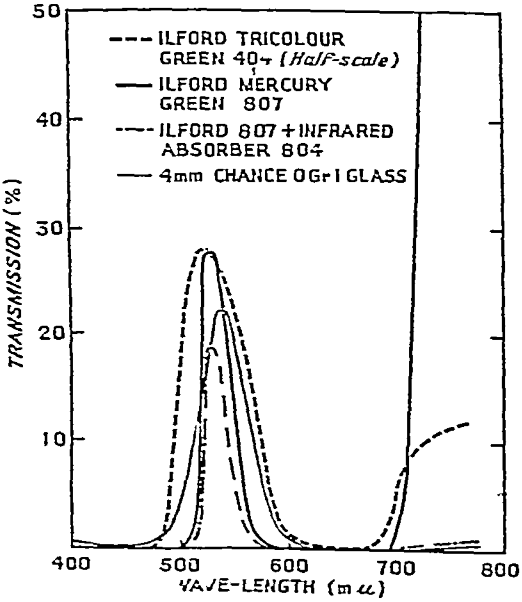

Fig 3—Transmission curves of monochromatic filters.

These results indicate that estimations with a simple absorptiometer, calibrated from table IV without reference to iron determinations, are comparable in precision and accuracy with those made by the most reliable spectrophotometric methods Most of the quotients by each method are in error by less than 1·5% In the case of cyanmethæmoglobin there is probably some systematic difference connected with the making of the solutions, since the standard deviation is less than 1·5, and hence the standard deviation of the mean, so far as measurement is concerned, is less than 0·5%

It is also significant that the standard deviations, as indices of accuracy, are very close to those obtained in paper V as indices of precision. This suggests that the stage has been reached where the uncertainties of optical calibration are less than those associated with the blood itself—the biological variations and the errors in taking the blood and making up the solutions It seems then that any further increase in the accuracy of hæmoglobin determinations now depends primarily on factors other than optical measurement

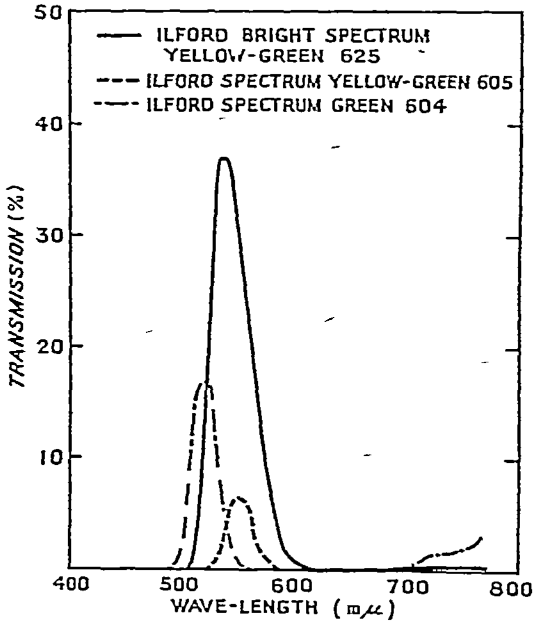

Fig. 4—Transmission curves of monochromatic filters.

DISCUSSION

The tables are intended primarily for the convenience of research-workers and of standardising laboratories undertaking the calibration of hæmoglobinometers, but they will prove useful to any manufacturer or user who wishes to calibrate his own instruments on an absolute basis Tables II and III are of such specialised application that comments on them are outside the scope of this paper Tables IV and V are those which will be more generally useful

The Measuring Instrument

If the instrument is to warrant calibration it must have a satisfactory performance. For a photo-electric instrument this implies that it should give a repeatable reading for a given solution and that there should be no creep, fatigue, or instability as shown by the galvanometer or milliammeter Inconstancy of zero reading and inconstancy of full scale reading are also symptoms of trouble which satisfactory instruments should not have In a visual instrument the readings should be independent of the exact position of the eye, if the field goes out of balance when the eye is moved across the eyepiece, a large spread in readings will result With a good visual photometer the standard deviation ought not to be greater than 0 007 in density—i e , about 1 5% on the Haldane scale Other features requiring attention are the depth and the shape of the liquid container Absolute standardisation with circular tubes is very unsatisfactory, and for commercial instruments almost impossible Cells with flat and parallel sides are essential, located at right angles to a parallel beam of light The depth of liquid traversed ought to be between 5 and 20 mm If it is less than 5 mm , the cells are difficult to clean, and if more than 20 mm , the alteration in path length in some instruments may cause errors There may be departures from Beer's law if the liquid layer is very much greater than the standard 10 mm

Choice of Filter

If a satisfactory hæmoglobin derivative and a satisfactory measuring instrument have been decided on, there remain the choice of a suitable filter and the calibration of the instrument It can be seen from table IV that the density depends on the derivative used, the nature of the green filter, and the type of measurement, visual or photo electric The table provides not only the absolute density value, but also, in conjunction with table V, the other information necessary for the choice of a suitable filter for any given set of conditions

For a photo electric instrument the choice of filter depends on departure from Beer's law and on the amount of light transmitted by the filter and hæmoglobin solution in combination Although the absorption of a solution is generally proportional to concentration of hæmoglobin for monochromatic light, the proportionality does not necessarily hold exactly when a band of wave lengths is used, as in the case of the green filters The departure from Beer's law is due to the fact that the spectrum band of green light passed by the filter is selectively absorbed by the hæmoglobin solution and altered in composition Now, the alteration in composition of the light varies with different concentrations, hence strict proportionality is not maintained Ilford 605 is the most nearly monochromatic of the selected filters, and does not show any serious departures from Beer's law Ilford 807, however, can give serious errors when used in photoelectric instruments, because of its rise in transmission at the red end of the spectrum (fig 3) This characteristic does not upset visual results to the same extent, because the eye is relatively less sensitive than the photocell in the red region, and because there is relatively less red in daylight than in the tungsten lighting used for photo electric work

When a filter of narrow bandwidth is selected to minimise the above effect it may have such a low transmission that the instrument becomes unworkable A transmission of less than 2% in table V makes working conditions difficult, unless there is special provision for high illumination or a highly sensitive galvanometer

For example if in a visual instrument the field brightness before insertion of the filter and solution is 100 the brightness will be reduced to 2 3 when a solution of oxyhæmoglobin is viewed through an Ilford 807 filter The strength of the solution is given as a percentage of 14 80 g per 100 ml

In choosing a filter, therefore, there must be a compromise between the mutually exclusive qualities of narrow bandwidth and high transmission

To take a specific example, if oxyhæmoglobin is to be estimated photo electrically, table V shows that most light is available with filter 404, then 625, 807, or OGr1 Departure from Beer's law is serious with 807, and not very satisfactory with 404 There is little to choose between 625 and OGr1 on this score, and, since there is twice as much light available when 625 is used (4% against 2% for OGr1), it is the most satisfactory of the selected filters for the purpose

TABLE VI—ACCURACY OF HÆMOGLOBIN ESTIMATIONS

Quotient against iron	Oxyhæmoglobin	Carboxyhæmoglobin	Acid hæmatin	Alkaline hæmatin	Cyanhæmatin	Cyanmethæmoglobin
	Photo electric absorptiometer calibrated by reference to table IV					
Mean S D	99 7 1 51	100 5 2 10	98 0 1 85	99 8 2 79	101 3 1 42	102 0 1 22
	Spectrophotometer and colour calculation					
Mean S D	100 3 1 17	100 1 1 19	101 1 2 12	100 8 2 71	101 7 0 71	102 6 1 40

For visual instruments the same factors have to be considered, and there is also, with some combinations of derivative and filter, the problem of colour differences These arise when the filter is used to view adjacent optical fields, one neutral grey and the other illuminated through the derivative They are given in table IV as "steps," each step being the least perceptible difference With oxyhæmoglobin the same four filters permit the greatest amount of light, but there is this time little to choose between them as far as departures from Beer's law are concerned However, colour difference rules out filter 404, and 807 transmits less than is desirable A colour step of one unit in the table is the most that can be tolerated for work of high accuracy, hence either 625 or OGr1 is satisfactory in this respect Since there is more light available with 625 it is the probable choice for visual estimations by the oxyhæmoglobin method

After a decision has been reached on the choice of filter, the instrument has to be calibrated absolutely, since it is desirable that it should provide and maintain its own optical standard independent of any material standard This can best be done by having the instrument calibrated under stipulated conditions at a suitably equipped laboratory such as the National Physical Laboratory The results are usually issued as instrumental readings which are equivalent to, say, 50, 100, and 120% Haldane for the particular blood derivative used

Optical Cell Instruments

Alternatively the worker with an instrument taking optical cells can use an already calibrated neutral grey screen to provide an unvarying reference point This is already a feature of the M R C photometer, and the makers* will also supply glass neutrals for use with any method of hæmoglobinometry Details of green filter, derivative, concentration, cell thickness, and required superficial dimensions should be given in addition to the type of receptor—i e, the eye or photocell. The most convenient density for such a standard is the "100%" value, though other values can be obtained if required for checking linearity The neutral grey screen has to be calibrated for green light, since the absorption curve is never sufficiently flat to justify the assumption that the absorption is the same for white and green light, and it is important to confirm that the optical conditions under which it is calibrated are the same as those which occur in the absorptiometer

The use of such a checking standard gives not only a correction to the instrument readings but also a check on constancy over a period It also shows what is the upper limit of error and gives confidence in the results by removing the possibility of gross hidden errors Once the error at the "100" point has been determined with the neutral glass screen, the errors at other parts of the scale can be checked by neutrals of other known densities, or by using a neutral grey solution at full strength, half strength, &c (Thomson 1946) If a hæmoglobin derivative is used for this purpose, allowance must be made for the departures from Beer's law given in table IV

Test tube Instruments

The calibration of test tube instruments, as mentioned above, is far from straightforward or satisfactory, but

TABLE VII—RESPONSE CURVE OF SELENIUM PHOTOCELL

Wave-length (mμ)	Spectral sensitivity	Wave length (mμ)	Spectral sensitivity
400	619	600	912

570	996	770	8
580	986		
590	958		

The values given above are derived from data supplied by Messrs Harding and Preston of the National Physical Laboratory the following procedure may be used to provide a fairly reliable calibration.

---

* Messrs C Davis Keeler Ltd 39 Wigmore Street London W 1

The internal diameter and uniformity of the tubes can be checked by filling them with a strong neutral† or hæmoglobin solution and observing any variation in readings with rotation or interchange. If variations are found, the tube must be used in a fixed orientation and corrections made for differences between tubes. It must be remembered that the difference often depends on the density being measured.

The next stage is to measure in the tubes a neutral solution known to have the same density as the "100%" value of the chosen derivative and filter or, alternatively, a neutral solution to which a definite "% value" has been assigned. For workers with both optical cell and test-tube absorptiometers the neutral solution could be calibrated in the square cell against a standardised glass neutral. The density obtained can then be expressed on the hæmoglobin scale by use of table IV, hence, when the solution is used in the test tube, the scale reading obtained can be correlated with hæmoglobin.

Where these facilities are not available, an already calibrated neutral solution may be obtained from the makers of the glass neutrals. The same details of derivative, filter, &c., should be given.

Measurement of the neutral solution in the test tube provides the instrument reading which would be obtained from a blood of the equivalent strength quoted (or determined) for the neutral. Calibration at other concentrations can then be made by using successive dilutions of the neutral solution. This method does not provide a scale of true optical density, but it gives a reliable scale of hæmoglobin content.

A glass neutral should still be used with test tube instruments to check constancy over a period. The filter need not be of known density, but its reading in the instrument should be noted during the original calibration, and the value obtained can be checked periodically.

Interconversion of Results

The tables can also be used to correlate the results obtained by different methods or with different filters. Suppose that an M.R.C. photometer is to be used with the carboxyhæmoglobin instead of the oxyhæmoglobin for which it is designed. The Ilford 625 filter fitted to it would give too large a colour difference with carboxyhæmoglobin (2·3 steps), but Ilford 807 would be satisfactory. Table IV gives a density of 0·475 for oxyhæmoglobin with 625, and 0·532 for the carboxy derivative *plus* 807, hence a blood of strength 100% Haldane would be expected to give a reading of 100 × 0·532/0·475 = 112 when estimated by the carboxyhæmoglobin method in an M.R.C. photometer fitted with 807 filter. Thus a correction factor could be applied to the scale readings so that results could be obtained easily on the Haldane scale.

A similar procedure can be followed for photo electric instruments when a change of derivative or filter is required. Suppose that an absorptiometer has been calibrated for use with oxyhæmoglobin measured via an Ilford 605 filter, and it is found that a scale reading of 0·470 is equivalent to 100%. Then, if estimations by the alkaline hæmatin method are required, the new 100% point can be computed from table IV. The true densities for oxyhæmoglobin and alkaline hæmatin are 0·498 and 0·510 respectively, hence the new scale reading for 100% by alkaline hæmatin is 0·470 × 0·510/0·498 = 0·482.

If the filter is to be changed from 605 to, say, Chance OGr1, the new 100% point for oxyhæmoglobin will be 0·470 × 0·431/0·498 = 0·406.

In this way changes of filter and derivative can be made without the necessity for a lengthy practical recalibration.

Some Variables

Although the data in the tables can be relied on for most work, there are some variables which must be taken into account for work of the highest accuracy. The most important of these concerns the filter. The density values for 100% strength have been calculated on a defined filter transmission curve—the mean of a number of samples of the filter. A filter of the same name will have a transmission curve close to the mean, but may show quite definite differences from it. Unfortunately, these differences are not just due to a variation in the concentration of dye in the filter gelatin. The dye is usually composite, and there are present also variations in the shape of the transmission curve. When the density curve of the hæmoglobin derivative is reasonably flat—e.g., as in the compounds acid or alkaline hæmatin—the variations in filter transmission have a diminished influence on the standard density value. With oxyhæmoglobin or carboxyhæmoglobin considerable variations in density take place even in the range of wave lengths transmitted by the filter, and consequently any change in the shape of the transmission curve of the filter affects the standard density. This possibility of significant variation in commercial filter production makes the filter the most uncertain element of the absorptiometer when considered as an absolute measuring instrument. If, however, the filter transmission had been measured, and the precise optical densities for a given solution calculated by the method given in the appendix, this doubt is removed. An efficiently working absorptiometer or photometer will then merit comparison with the spectrophotometer so far as that particular coloured solution is concerned.

The energy distribution of the lamp, or the response curve of the eye or the photocell are variables which have relatively little influence on absorptions, but in visual instruments there may be an appreciable change in colour difference with change in illuminant—e.g., from daylight to tungsten filament lamp.

Conclusion

It is realised that this detailed information does not cover all aspects of the choice of a suitable technique of hæmoglobin estimation. There are so many other factors, such as practicability, cost, personal taste, and tradition, which influence the choice, that a judgment on the above-mentioned data alone would not be universally accepted. At the present stage the objective has been limited to showing what can be done by modern optical technique to further hæmoglobinometry, and to indicate the aspects which can be treated with mathematical exactitude.

SUMMARY

The principles involved in the optical standardisation of hæmoglobinometers are discussed.

Tables of the visible spectral absorption of six hæmoglobin derivatives are given, together with calculated data which apply to different types of instrument.

An experiment to test the precision obtainable with purely optical standardisation is described.

The use of the tabulated data is discussed with reference to the selection and routine use of hæmoglobin methods.

The desirable performance of accurate hæmoglobinometers is discussed, and procedures for calibration are given, together with details of a service for providing neutral checking standards.

Tests of instruments calibrated from the tabulated values indicate that any further increase in the accuracy of hæmoglobin determinations depends on technique and biological factors rather than optical factors.

This investigation has been made for the Medical Research Council's subcommittee on analytical methods. The expenses were partially defrayed by a grant from the Medical Research Council, to whom grateful acknowledgment is made. Our thanks are due to Sir Charles Harington, chairman of the subcommittee on analytical methods, for much valuable

---

† A reliable neutral solution of adequate strength is described by Thomson 1946.

advice, and to the patient and willing observers Colour and absorption measurements were made at the National Physical Laboratory on behalf of the Medical Research Council.

Appendix

In deriving the standard optical densities of table IV the following data are required

(1) The spectral transmission, Tλ, of a 1 cm. layer of the hæmoglobin derivative of strength 14 80 Fe per 100 ml. at 1 200 dilution. This is derived from table I by the usual method of first finding the density for the required concentration and thence the transmission. Tλ is the transmission at wave length λ and is tabulated at wave length intervals of 10 mμ throughout the visible spectrum

(2) The spectral transmission, tλ, of the green filter at the same wave length intervals These values result from a spectro-photometric measurement of the filter

(3) The spectral energy distribution of the illuminant Eλ. For visual instruments this is taken as daylight, and for photo-electric instruments as a gas filled tungsten lamp of low wattage. The appropriate data have been published by Wright (1944) under the designations "illuminant B" and "illuminant A"

(4) The response curve of the eye, Vλ, and of the photo cell, Sλ. The curve Vλ or luminosity function is found in Walsh's (1926) book or any other book on photometry. Values for Sλ are given in table VII. These are characteristic of the usual selenium barrier layer cell The values of Eλ, Vλ, and Sλ at 10 mμ intervals can easily be found from these references

The magnitude of the eye response before the hæmoglobin solution is interposed is given by

$$\int E\lambda\, V\lambda\, t\lambda\, d\lambda,$$

the range of integration being the visible spectrum 40μ–76μ Such an integral can be calculated numerically by the method of summing the ordinates. Each product Eλ Vλ tλ is found at each wave-length 0·40, 0 41 0·42μ, &c, and the results are summed over the range 0 40μ–0 76μ. When the solution is interposed, the response is

$$\int E\lambda\, V\lambda\, t\lambda\, T\lambda\, d\lambda,$$

hence the transmission is

$$\int E\lambda\, V\lambda\, t\lambda\, T\lambda\, d\lambda / E\lambda\, V\lambda\, t\lambda\, d\lambda.$$

When a photocell is used, Sλ is substituted for Vλ. The optical densities for each filter and derivative at strength of 100% Haldane scale are thus found

Similarly the densities for 120 80, and 40% Haldane scale can be calculated to show the departures from Beer's law

The colour differences are found from calculations of a similar type to those given above Instead of Vλ, the luminosity function, there are substituted the three trichromatic colour functions of the eye Full details of this calculation have been given by Wright (1944) and MacAdam (1942)

RADIOLOGICAL DIAGNOSIS OF EMPHYSEMA

J M S KNOTT
M.B Camb, M.R C.P

RONALD V CHRISTIE
M.D Edin., D.Sc Lond., F.R C P

From the Medical Professorial Unit, St Bartholomew's Hospital, London

THE diagnosis of florid emphysema is usually a simple matter, but most physicians would agree that in its early stages the so called physical signs of this condition may be unreliable or even misleading For this reason several special diagnostic procedures have been advocated, but as a rule the one most readily available in hospitals is radiography of the chest It has been claimed that emphysema presents characteristic radiological appearances, and the purpose of the investigation described here was to test this claim

METHOD

Twenty patients, aged 45–60, with a clinical diagnosis of moderate or severe emphysema, were selected from an outpatient clinic Each of these patients had the physical signs of emphysema together with a history of chronic bronchitis for many years and more recently a history of increasing breathlessness on exertion which could not be explained on any basis other than emphysema itself. Each patient was assessed on the basis of physical signs and symptoms and placed in one of two categories, moderate or severe As a control, 20 patients of the same age group were selected in whom there was no evidence of chronic bronchitis, asthma, or any other abnormality of the cardiovascular or respiratory systems In both groups radiograms of the chest were taken in four positions postero anterior and lateral, on full expiration and on full inspiration These were numbered at random and submitted to a physician and three radiologists, all of whom may be considered to have had special experience in this field (Dr P J Kerley, director of the X ray department, Westminster Hospital and the Royal Chest Hospital, Dr R A Kemp Harper, director of the X ray department, St Bartholomew's Hospital, Dr G Simon, assistant radiologist, St Bartholomew's Hospital, and assistant director, radiological department, Brompton Hospital, and Dr. N C Oswald, assistant physician, St Bartholomew's Hospital, and assistant physician, Brompton Hospital) The observers were given a pro forma so that their opinions on the radiological features could be comparably recorded At least one of the observers knew that there was an equal number of controls and patients with emphysema Although this information should not have been given in such an investigation, it does not invalidate the conclusions

The first part of this investigation consisted in the assessment of the postero anterior and lateral films on full inspiration and full expiration on the following criteria

Postero-anterior Chest Films—In emphysema the thoracic cage is usually large and the diaphragm may be low, flat and irregular Hypertrophy of the pectoralis muscles may be seen The ribs may tend to lie horizontally, and the intercostal spaces and subcostal angle may be wide The heart may appear to lie vertically, with a prominent pulmonary conus and exaggerated pulmonary arterial shadows at the lung hila. The medium-sized vessels tend to stand out more clearly but are smaller in calibre than normal The smaller peripheral vessels may also be more clearly visible than normal. The lung fields may show increased translucency, particularly at the lung bases Individual bullæ may be seen, usually at the apices of the lungs

Lateral Chest Films—The thoracic cage is large and there is often kyphosis affecting all the dorsal vertebræ The diaphragm is usually low, and its movements on inspiration and expiration, as well as those of the sternum, may be diminished The space between the sternum and the heart is almost invariably increased In other respects the lateral films confirm the appearances seen in the postero anterior films

RESULTS

Of the 20 patients with emphysema, all four observers made a correct diagnosis in 14 cases, three observers being in agreement on another 4 In 2 cases (nos 20 and 30) three observers were of the opinion that emphysema was not present Of the control group, 4 were diagnosed as having emphysema, in each case by only one of the observers This part of the investigation suggests that a fairly reliable diagnosis of emphysema can be made from postero anterior and lateral films taken on inspiration and expiration, 70% of the emphysema group and 80% of the control group were correctly diagnosed by all the observers Assessment of the degree of emphysema showed a wide divergence of opinion among the four observers (table I)

The provision of both postero anterior and lateral films in full inspiration and full expiration gave the observers more evidence than is commonly available even in the best of departments In most hospitals only a postero anterior film on full inspiration is provided For this reason both patients and controls were assessed again, and on this occasion the only evidence submitted was the postero anterior film on full inspiration The results of this part of the investigation are set out in table II The four observers agreed on the diagnosis of emphysema in 15 cases, three agreed on a further case (no 34) and one diagnosed emphysema in another 3 cases (nos 3, 20, and 40) All were in agreement on the absence of emphysema in 1 case (no 30) There was, however, considerable disagreement on the normal group, no less than 12 of the controls being diagnosed as having emphysema

These results indicate that a diagnosis of emphysema based on a postero anterior film may be misleading 75% of the emphysema group were correctly diagnosed, but only 40% of the controls were passed as normal by all the observers

It is generally agreed that it is often difficult to make a dogmatic clinical diagnosis of emphysema, and consequently the observers might contend that at least 4 of the emphysema cases (nos 3, 20, 30, and 40) had in fact normal chests The relevant clinical and laboratory findings in these 4 cases were as follows

Case 3 —A labourer, aged 60, had had winter bronchitis for fifteen years and dyspnœa, which prevented him from working, for two years

On examination there was no cyanosis, but climbing a flight of stairs caused dyspnœa The chest was barrel shaped, with poor expansion No area of cardiac dullness was apparent. Expiration was prolonged, and there was minimal diffuse bronchospasm The blood pressure was 116/74 mm Hg

Clinical Diagnosis —Severe emphysema

Physiological Data *—Vital capacity, 1700 ml , functional residual air, 4583 ml , mixing efficiency, 40%, residual air (expressed as percentage of total lung volume), 75%, and CO_2-combining power, 74 vol %

Case 20 —A postman, aged 45, had had chronic cough with winter exacerbations for ten years and dyspnœa for four years He could walk only 40 yards

On examination there was no cyanosis, but exertion caused dyspnœa The chest was barrel shaped, with dorsal kyphosis, poor air entry, and moderate diffuse bronchospasm The blood pressure was 106/70 mm Hg

---

*The physiological data were recorded by the methods used by Bates and Christie (1950)

phosis	10	10 5	2	4 0
rizontal ribs	3	7 5	0	2 5
lcification of costal cartilages	6	11 5	5	11 0

Clinical Diagnosis —Moderate emphysema

Physiological Data *—Vital capacity, 3320 ml., functional sidual air, 4243 ml., mixing efficiency, 43 5%, residual r as percentage of total lung volume, 51%, and CO_2 mbining power, 70 vol %

Case 30 —A theatre orderly, aged 46, had had cough with utum and winter bronchitis for fourteen years and dyspnœa n moderate exertion for five years

On examination there was no cyanosis, and the chest was rrel shaped, with no area of cardiac dullness, and with rolonged expiration, moderate diffuse bronchospasm, and attered basal râles The blood pressure was 120/78 mm Hg

Clinical Diagnosis —Moderate emphysema

Physiological Data *—Vital capacity, 1710 ml functional sidual air 2530 ml, mixing efficiency, 32%, residual air s percentage of total lung volume, 55%, and CO_2 combining ower, 60 vol %†

Case 40 —An electrician, aged 60, had had cough with putum for five years and dyspnœa on exertion for four years

On examination there was no cyanosis, and the chest was arrel shaped, with generalised thoracic kyphosis, no area of ardiac dullness, hyper resonant percussion note, prolonged xpiration, and poor air entry The blood pressure was 120/70 nm. Hg

Clinical Diagnosis —Moderate emphysema

Physiological Data *—Vital capacity, 2370 ml, and CO_2-combining power, 69 vol %

This patient died in February, 1948 so further investigations were not made No necropsy was performed.

The pro formas contained ten radiological signs said commonly to be associated with emphysema, and three of the observers were asked to comment on their presence or absence in the 40 cases. The incidence of these signs is shown in table III, and it is clear that most of them, if taken alone, are of doubtful diagnostic significance, since they may be absent in emphysema and are not infrequently present in those without emphysema

The measurements of diaphragmatic movement in this series showed an average range of 1 5 cm in the emphysema cases and 3 3 cm in the controls These figures are of little diagnostic significance, for 7 controls had diaphragmatic movement of less than 3 cm and 3 emphysema cases had more than 3 cm of movement

The relative importance of the various criteria is of interest because features such as horizontal ribs, wide rib spaces, and calcification of the costal cartilages have been used as radiological evidence for many years and their validity scarcely questioned This investigation shows that many of these features can be seen in people of late middle age who, so far as one can tell from clinical and physiological studies, have not chronic hypertrophic emphysema

DISCUSSION

The diagnosis of chronic hypertrophic emphysema, whether by clinical, radiological, or physiological tests, has always presented great difficulties Cabot (1930) was early to recognise the pitfalls in clinical diagnosis by the so called characteristic physical signs, and thought that emphysema could only be recognised by "careful radiological study" The problem of the radiological diagnosis has received scant attention in radiological textbooks and medical reports Most workers name some features which they consider to be important but make little attempt to analyse the relative significance of features which have been passed from one book to another without comment For example, Köhler (1935) emphasises the diagnostic importance of the increased retrosternal space, Holmes and Ruggles (1931) the hypertranslucency of the lung fields, and Sante (1930) the accentuated peribronchial markings and the formation of a reticular pattern in the peripheral lung fields Fray (1934) has rightly emphasised the importance of fluoroscopy in the diagnosis of emphysema because features such as hypertranslucency of the lung fields and diaphragmatic excursion are more easily appreciated thereby

SUMMARY

A radiological diagnosis of emphysema based on a single postero anterior film on full inspiration is of doubtful significance

A more reliable assessment may be made from films taken in the postero anterior and lateral positions, in both inspiration and expiration, but even on this evidence about 10% of cases will be missed and a few normal persons wrongly diagnosed as having emphysema

The radiological features of emphysema are discussed.

We wish to thank M. P Curwen for statistical advice and assistance

COSTAL CHONDRITIS (TIETZE'S DISEASE)

E H W DEANE
M.B Melb
CONSULTANT CHEST PHYSICIAN, MANCHESTER REGION

Tietze (1921) first described, in 5 cases, a condition which was characterised by painful non suppurative swelling of costal cartilages and only slowly resolved It was thought at the time to be related to malnutrition after the 1914–18 war Other cases were subsequently recorded in Germany and Japan, and Gill et al (1942) reported 5, and Acharya (1944) 2, in Service personnel in this country Geddes (1945) described 22 cases in Canadian Servicemen In the Service cases there was no evidence of malnutrition

In most of the more recently reported cases the association of a respiratory lesion has been noted, usually this has been a "cold" or bronchitis, but occasionally a definite pneumonia has been present This association with respiratory infection was first noted by Gill et al (1942) and confirmed by Geddes (1945), who found it in all his patients In no case has a tuberculous lung lesion been noted

The condition is usually called Tietze's disease, but a more anatomical description seems desirable and the term costal chondritis seems suitable

In the past few years I have observed 7 cases (I can also remember 2 earlier cases, though I have no records tion and expiration, as well as those of the sternum, may be diminished The space between the sternum and the heart is almost invariably increased In other respects the lateral films confirm the appearances seen in the postero anterior films

---

† It is of interest that the functional residual air in case 30 is within normal limits and that the mixing efficiency in cases 3 and 20 is higher than has been found in other cases of emphysema

RESULTS

Of the 20 patients with emphysema, all four observers made a correct diagnosis in 14 cases, three observers being in agreement on another 4 In 2 cases (nos 20 and 30) three observers were of the opinion that emphysema was not present Of the control group, 4 were diagnosed as having emphysema, in each case by only one of the observers This part of the investigation suggests that a fairly reliable diagnosis of emphysema can be made from postero anterior and lateral films taken on inspiration and expiration, 70% of the emphysema group and 80% of the control group were correctly diagnosed by all the observers Assessment of the degree of emphysema showed a wide divergence of opinion among the four observers (table I)

The provision of both postero anterior and lateral films in full inspiration and full expiration gave the observers more evidence than is commonly available even in the best of departments In most hospitals only a postero anterior film on full inspiration is provided For this reason both patients and controls were assessed again, and on this occasion the only evidence submitted was the postero anterior film on full inspiration The results of this part of the investigation are set out in table II The four observers agreed on the diagnosis of emphysema in 15 cases, three agreed on a further case (no 34) and one diagnosed emphysema in another 3 cases (nos 3, 20, and 40) All were in agreement on the absence of emphysema in 1 case (no 30) There was, however, considerable disagreement on the normal group, no less than 12 of the controls being diagnosed as having emphysema

These results indicate that a diagnosis of emphysema based on a postero anterior film may be misleading 75% of the emphysema group were correctly diagnosed, but only 40% of the controls were passed as normal by all the observers

It is generally agreed that it is often difficult to make a dogmatic clinical diagnosis of emphysema, and consequently the observers might contend that at least 4 of the emphysema cases (nos 3, 20, 30, and 40) had in fact normal chests The relevant clinical and laboratory findings in these 4 cases were as follows

Case 3 —A labourer, aged 60, had had winter bronchitis for fifteen years and dyspnœa, which prevented him from working, for two years

On examination there was no cyanosis, but climbing a flight of stairs caused dyspnœa The chest was barrel shaped, with poor expansion No area of cardiac dullness was apparent. Expiration was prolonged, and there was minimal diffuse bronchospasm The blood pressure was 116/74 mm Hg

Clinical Diagnosis —Severe emphysema

intoxication, hypotonia is apparently most common, but he noted convulsions in 3 cases. Debre has had 2 fatal cases (in children aged twenty and sixteen months who had received respectively 11,200,000 and 18,200,000 units), one apparently due to uræmia and the other to subarachnoid hæmorrhage. In a third case the patient survived with hemiplegia and mental deficiency. Debré concludes that the real dangers are cerebral and renal impairment. THE LANCET (1946) stated that 'signs of central nervous system involvement, such as apraxia, aphasia, convulsions, and cerebral vascular accidents, have been noted in the terminal stages of fatal cases." On the other hand, Anning et al. (1948), reviewing the toxic effects of calciferol in 200 cases do not mention convulsions. Nor does Macrae (1947) in an analysis of 20 hospital cases, although 2 elderly patients suffered severe cerebral damage. It therefore seems that, with severe intoxication, signs of cerebral damage are common but convulsions, in the absence of uræmia or cerebral vascular accidents, are very rare.

CASE RECORD

A man, aged 20 who had been treated continuously since Sept. 17, 1948 with 'High Potency Ostelin' (Glaxo) 150,000 units by mouth daily for papulonecrotic tuberculide, was admitted to the Royal Victoria Hospital on July 8, 1949, after an epileptiform attack, observed by his doctor at home on the previous day. Another general convulsion was observed by the ward sister shortly after his admission. Three weeks previously he had complained of severe pains in the jaws. These had increased in severity but could be partly relieved by aspirin. Shortly after the onset of these pains his parents had noticed that he was becoming increasingly drowsy. At the same time he had complained of anorexia and, shortly before the first fit, of vomiting and colicky abdominal pain.

Previous History.—His birth was normal, there was no history of convulsions in childhood, nor were there any neurotic traits. At no time was he exposed to lead intoxication. He developed papulonecrotic tuberculide about September, 1945.

In October, 1947, radiography of his chest suggested pulmonary tuberculosis, and he rested in bed for 2 months. In January, 1949, he was operated on for gall-bladder empyema and subhepatic abscess.

Family History.—His father, mother, one brother, and one sister were alive and well. One brother had died at the age of 18 with congestion of the lungs. There was no family history of epilepsy, "faints," nervous ailments, or deformities.

On admission he was drowsy, disoriented in time, place, and person, and complained of severe pains in the jaws. His skin was pale and dry. His temperature was 99·5°F, pulse-rate 92, and blood-pressure 140/95 mm. Hg. There had been a short period of amnesia from just before the first convulsion, but he was aware of his surroundings on the day after admission. Except for this abnormal mental state and the presence of bilateral extensor plantar responses no other abnormality was noted. Severe calciferol intoxication was provisionally diagnosed.

Treatment.—The calciferol was stopped and intramuscular soluble phenobarbitone and a low calcium diet were given.

Progress.—The mental state improved slowly until the patient was fully oriented and his normal personality was displayed as that of a cheerful intelligent man. At this time complete formal clinical examination was negative in all respects, apart from his skin condition, despite the fact that his blood-calcium level continued to be raised. He was correctly oriented when the first electro-encephalogram (E.E.G.) was recorded. The papulonecrotic tuberculide was not influenced appreciably by the treatment. Apart from an isolated record of 140/95 mm. Hg on admission all subsequent readings of the blood-pressure were about 120/80 mm. Hg.

Electro-encephalography was first carried out twelve days after the second and last convulsion. The E.E.G. was abnormal, showing excess of delta and theta activity of moderate amplitude largely replacing the alpha rhythm, which was then at 8 cycles per sec. The serum-calcium level was then 14·5 mg. per 100 ml. Subsequent E.E.G.s slowly improved as the blood-calcium level returned to normal four months later (see figure). The last serum-calcium level was 9·8 mg. per 100 ml., the E.E.G. then showed only occasional theta activity of low amplitude, and the alpha rhythm was 8–12 cycles per sec. There was also occasional low-amplitude faster activity at 16–20 cycles per sec. Nothing diagnostic of epilepsy was noted.

Renal Function.—Initially there was slight albuminuria. This cleared completely in nine days, but some months later a faint trace of albuminuria was occasionally noted. Intravenous pyelography on Oct. 7, 1949, was normal. The blood-urea level on July 21, 1949, was 65 mg. per 100 ml., and the blood uric acid level on Jan. 31, 1950, was 4·3 mg. per 100 ml. There is some evidence of slight impairment of renal function seven months after cessation of calciferol therapy. The state of renal function before calciferol was given is not known.

Cerebrospinal fluid on Aug. 5, 1949, was normal.

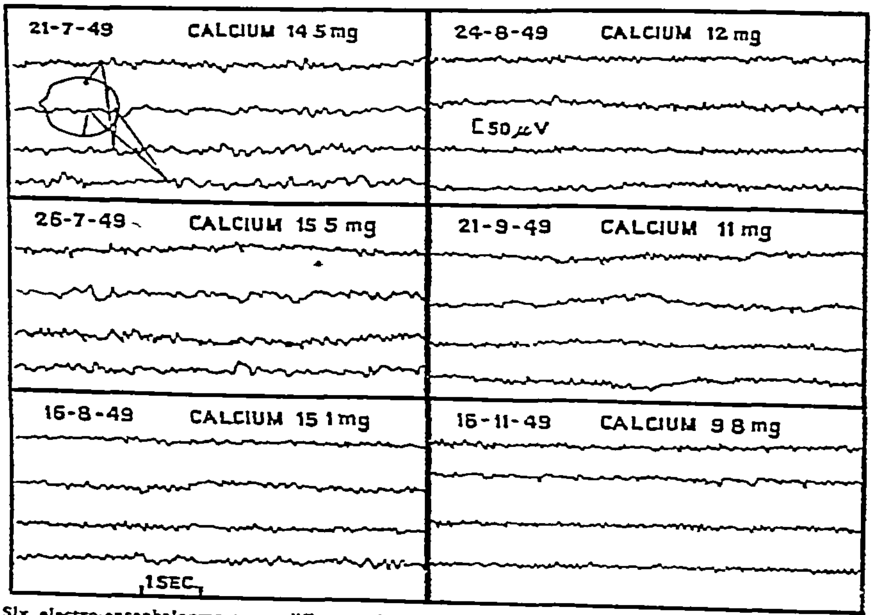
White-cell count on July 15, 1949, showed 9750 leucocytes per c.mm. (neutrophils 83%, eosinophils 1%, basophils 1%, lymphocytes 10%, monocytes 5%).

Wassermann and Kahn reactions were negative.

Radiography of the long bones showed no decalcification, and of the chest showed tuberculous lesions in both upper zones and in the left mid-zone. There was no evidence that calciferol adversely affected the pulmonary tuberculosis.

DISCUSSION

Calciferol was used in this case in the daily dosage recommended by Dowling and Thomas (1945) for lupus vulgaris. Apart from two weeks during which he had been in hospital with gall-bladder empyema the patient had taken calciferol continuously, and without routine hospital surveillance, for nine and a half months. So far as we know, he did not at any time exceed a daily dose of 150,000 units.



Six electro-encephalograms at different dates from the same electrode positions as indicated in the first record. These records were made with the eyes closed. There was gradual improvement and return to normal as the blood-calcium level fell.

of them) All the 7 patients were civilians, 5 were males and 2 were females, and their ages ranged from 13 to 46 In 5 there was associated infection of the respiratory tract There was never any evidence that the condition had been caused by injury

CASE RECORDS

Case 1 —A male clerk, aged 40, had a painful swelling of the second right costal cartilage, and the pain was aggravated by a slight cough which he had had for a few weeks Examination revealed a slightly tender swelling of the second cartilage, over which the skin and subcutaneous tissues could be moved freely Deep breathing, coughing, or movement of the right arm caused pain There were no physical signs of a lesion in the lungs, and a chest radiography was clear On the day before the pain and swelling appeared the patient had been erecting a flagpole, but he had no recollection of any injury or strain while so engaged Local application of heat and a sling for the arm were prescribed, and the tenderness and pain decreased and disappeared in three weeks, but some swelling of the cartilage was still present when he was last seen three months later This, however, occasioned no disability

Case 2 —A collier, aged 28, had had for a week a similar painful swelling of the second left costal cartilage There were no associated respiratory symptoms and no history of injury Radiography of chest was clear Tenderness lasted for three weeks, after which the patient returned to work without disability, but some swelling was still present three months later

Case 3 —A painter, aged 30, had had a painful swelling of the second right costal cartilage for four days, without cough or evidence of respiratory infection. Pain disappeared a month later, and he returned to work six weeks after first being seen Some swelling of the cartilage was still present but it did not interfere with his work

Case 4 —A schoolgirl, aged 13, with swelling and pain in the second right costal cartilage, with no cough and no radiographic signs in the chest, had had a sore throat a fortnight before the swelling appeared The pain and swelling gradually subsided, but some thickening of the cartilage was still present three months later

Case 5 —A hawker, aged 46, had had a painful swelling of the second right costal cartilage a day before he attended the clinic The pain decreased and disappeared in four weeks, but there was still slight prominence of the cartilage twelve months later This man had had a tuberculous pleural effusion ten years previously, and radiography showed some hard nodular deposits in his right upper zone, but there was no clinical evidence of an active lesion He had a cough at the time of onset of the swelling, and some scattered rhonchi were heard in both lungs

Case 6 —A farm labourer, aged 25, had had a swelling of the second right costal cartilage for three weeks It had been painful and tender at the onset, but there was little pain and only slight tenderness when he attended the clinic All discomfort has since disappeared, although some swelling remained The patient had had a "cold" and some cough about the time of the onset, but all evidence of respiratory infection had cleared by the time he came for examination The chest was clear on radiography

Case 7 —A female clerk, aged 28, had had painful swelling of the left second and third costal cartilages for three days She had a cough, and rhonchi were scattered throughout both lungs, but X rays showed no abnormality in the chest, and there was no pyrexia Some swelling and discomfort was still present a month late, but subsiding Catarrhal sounds were still present in the lungs, and the chest remains radiographically clear

DISCUSSION

The cases which have come under my observation have all involved the second costal cartilage, but other workers have reported involvement of any, or in some cases several, cartilages from the first to the tenth Nevertheless the second seems to be involved more often than any other, and in my cases the right was affected more often than the left In only a few cases has a history of injury been obtained, and this may be coincidental rather than causal The swelling is confined to the limits of the costal cartilage, which feels thickened, whether this is due to the swelling of the cartilage or of perichondral tissues is difficult to determine clinically The swelling is sharply demarcated laterally by the costochondral junction, over which tenderness may be more acute than over the cartilage

In all the cases referred to me for an opinion the question of a tuberculous infection was at issue, but in none except case 5 was there any evidence of such an infection, and in this case the pulmonary lesion is regarded as inactive A feature of the condition seems to be that the swelling and pain reach a maximum within a day or two and then gradually subside over three or four weeks Some residual swelling may, however, remain indefinitely Geddes (1945) states that further respiratory infection may cause pain to recur in the cartilage, but this has not been my experience in this small series

Investigation of erythrocyte sedimentation rate, Wassermann reaction, and blood counts has not revealed any significant findings Biopsy has not been done in any of my cases, because it has not been thought justifiable in an essentially benign condition in outpatients, but biopsy in several other cases has shown little beyond a chondral and perichondral hyperplasia In no case has suppuration occurred, and no specific cause for the condition has been found beyond the frequently associated respiratory infection

Costal chondritis is probably more common than has been thought Though the pathological basis has not yet been determined, the patient may be reassured that the lesion is benign No treatment is necessary or likely to shorten the duration of the trouble, but rest of the arm on the affected side and the application of local heat when the swelling is painful give comfort

ADDENDUM

Since this article was completed 3 further cases, similar to those described here, have been observed

The more common symptoms of calciferol intoxication include thirst, anorexia, nausea, vomiting, tiredness, malaise, headache, and constipation or diarrhœa. Abdominal pain is a frequent complaint, and patients may be admitted to hospital as abdominal emergencies (Anning et al 1948) Apathy, drowsiness, and coma may occur as late symptoms (Debré et al 1946) Psychic disturbances and confused memory have been recorded (Covey and Whitlock 1946) Convulsions are extremely rare Bell (1949) recorded an example in a boy of 10 years who had taken by mouth a single ampoule of 'Sterogyl' containing 600,000 units of calciferol, in addition to a previously recommended course consisting of 50,000 units of calciferol by mouth twice daily This ampoule of sterogyl had been given a week before the onset of convulsions Dowling in a personal communication (MacKenna 1948) records that among his toxic patients "one child developed signs suggesting meningitis with neck rigidity and photophobia" Debré (1948) states that nervous symptoms may occur with severe

7				
10	4 05	2 65		
17			105 0	

On examination he looked ill, thin, toxic, and dehydrated, with conjunctival injection. There was diffuse tenderness over the lumbar muscles, particularly on the left side, and over the sacrum and pain in these areas on moving the legs In the abdomen, apart from a palpable pelvic colon loaded with fæces, nothing significant was felt A rectal examination after an enema was normal. There was no abnormality in heart or lungs, and the blood pressure was 145/80 mm. Hg The tendon reflexes were generally diminished, but the central nervous system yielded no other positive findings The retinæ were normal

His hæmoglobin was 13 5 g per 100 ml and the white cell count 12 000 per c mm The differential count showed 11% eosinophils but was otherwise normal. The urine was alkaline, sp gr 1 008, with only a trace of albumin and no cells or casts The blood urea level was 201 mg per 100 ml A fractional test-meal showed achlorhydria Tests for occult blood in the fæces were positive on three occasions and negative once

Treatment and Progress—He was given large amounts of fluid by mouth and intravenously but his blood urea never fell below 70 mg per 100 ml., and his dehydration was never really controlled His urinary output was 3–3¹/₂ litres a day, sp gr 1 008–1 010 On the sixth day in hospital his urine was tested for calcium with Sulkowitch's solution and gave a positive reaction. We next investigated his blood chemistry, with the results summarised in the accompanying table

Straight radiography of the abdomen did not demonstrate any renal calcification, and intravenous pyelography showed poor concentration but nothing else abnormal Radiologically there was no gross hypocalcification but in the skull there were several small circumscribed areas of bone absorption, which had moderately well-defined borders and ranged in size up to that of a small pea

Operation—In view of the patient's continued deterioration it was decided to explore the neck for a parathyroid adenoma and three weeks after admission this was done, but with negative result He died a week later without any great change in his general condition.

Necropsy (Dr G Stewart Smith)—There was dense hard infiltration of the stomach wall round a shallow epithelialised ulcer high up on the lesser curvature, and there were several masses of enlarged glands in the vicinity There was no pyloric obstruction Microscopically the growth was a spheroidal celled scirrhous carcinoma

The skull, the sternum, and a femur (the only bones examined) were infiltrated with neoplastic tissue The areas of infiltration in the skull corresponded to the areas of bone absorption shown in the radiogram The kidneys were enlarged the left was pale yellow, the right mottled with red. Corticomedullary definition was poor, and the cortex was swollen. Microscopically the tubules were dilated and there were many intracellular calcium deposits The glomerular tufts were generally swollen, and Bowman's capsule lined with cuboidal epithelium, showing occasional calcium deposits No parathyroid adenoma was found. There were no metastases apart from those in the bones and in the lymph nodes immediately adjacent to the stomach

DISCUSSION

Because of the absence of cardiovascular and retinal changes, and the fact that the patient had had large quantities of alkalis before admission, we originally treated him as a case of prerenal uræmia, but his lack of response soon made it clear that true renal failure was present Albright et al (1934) and subsequent workers have emphasised the importance of searching for a parathyroid adenoma in cases of unexplained renal failure That was why we sought for calcium in the urine and then investigated the blood chemistry We regarded our results as significant, and considered the renal failure sufficient to explain the high blood phosphorus level found instead of the low values usually found in hyperparathyroidism We did not consider that the minimal bone changes and absence of demonstrable calcification in the kidneys on radiography ruled out the diagnosis, for renal failure due to parathyroid adenoma may be present without severe bone changes (Albright et al 1934), and, although in many cases large renal calculi are formed, the deposition may be microscopic and yet lead to renal failure

Although, however, nephrocalcinosis is predominantly associated with hyperparathyroidism, and may be the presenting feature of that disease, it has been described in other conditions Martz (1940) described three cases, and reviewed others described previously, in which nephrocalcinosis occurred in association with hypochloræmia and alkalosis in the persistent vomiting of pyloric obstruction In such cases the blood calcium and blood chlorides levels are both low, and tetany often develops Martz suggests that the alkalosis in these cases is probably the cause of the calcium deposits in the kidneys Although our case does not come into this group, there was, on the two occasions on which it was estimated, an abnormally high alkali reserve, which may have played some part in the deposition of calcium In the two cases of nephrocalcinosis associated with hyperparathyroidism in which the alkali reserve was noted it was within normal limits (Albright et al. 1934, Bellin and Gershwin 1935)

Nephrocalcinosis may also occur in multiple myelomatosis (Perla and Hutner 1930), and may then present difficulties similar to those encountered here There is really no way of proving the presence of a parathyroid adenoma apart from exploratory operation, but we feel that a bone marrow biopsy would serve to exclude such cases as are due to myelomatosis or to a condition such as we have described here

Since seeing this case we have investigated cases of carcinoma with known bone secondaries, but have found none with hypercalcæmia or calcinuria—which suggests that the syndrome only develops in cases in which the bony secondaries are of sufficiently wide distribution or long duration If we assume that this patient's ulcer was malignant at the time of operation, the carcinoma had been present for at least eighteen months without causing local trouble or metastases in organs other than bone Presumably most patients with carcinoma, even with bone secondaries, die from some other cause before nephrocalcinosis has time to develop

The eosinophilia, which we could not otherwise explain, may have been due to the diffuse carcinomatosis of bone—a cause of eosinophilia described by Whitby and Britton (1942)

SUMMARY

A case of renal failure associated with hypercalcæmia is described

Nephrocalcinosis due to parathyroid adenoma was diagnosed but no adenoma was found at operation

At necropsy carcinoma of the stomach with multiple metastases in bones was found associated with nephrocalcinosis

Our thanks are due to Dr R W Luxton, under whose care the patient was to Dr G Stewart Smith, who carried out the

ELECTRO ENCEPHALOGRAPHIC FINDINGS IN 4 PATIENTS UNDER TREATMENT WITH CALCIFEROL

Case no	Sex	Age (yr)	Toxic symptoms	E E G	Serum-calcium level (mg per 100 ml)	Serum phosphorus level (mg per 100 ml)	Blood urea level (mg per 100 ml)
1	M	45	Polyuria and thirst (no bone pain no headache)	Normal	10 7	9 5 1	40
2	M	21	Polyuria and frontal headache (no thirst no bone pain)	Normal	10 8	6 0	60
3	M	10	None	Normal, no change 1 and 2 months after completion of treatment	11 6	6 5	20
4	F	40	None	Normal	10 8	6 0	43

There is no evidence that our patient suffered any cerebrovascular accident, nor was he uræmic Macrae (1947) has suggested that some of the toxic effects of calciferol may be due to immobilisation of lead from the bones There is no evidence of this in the present case Careful inquiries showed that our patient was not at any time exposed to lead intoxication There was no blue line, lead palsy, or abnormality of peripheral blood, and the response to treatment, which included a diet completely free from calcium, was dramatic

The E E G changes suggest a diffuse cortical toxic effect Diffuse changes follow an epileptic fit but usually resolve in a matter of days The first E E G was taken twelve days after the second (last) fit We have not been able to find published reports of E E G changes in hypervitaminosis or in hypercalcæmia Possibly the changes recorded here were due to the hypercalcæmia since the E E G improved as the serum calcium level fell, but the parallel was not exact Electro encephalography was done in 4 other patients under treatment with calciferol for lupus vulgaris (see table) It will be seen that the E E G were normal with and without toxic symptoms and that in each case the serum calcium level was normal Minor deviations of the blood-urea level up to 60 mg per ml cause little change in the E E G The "toxin" must therefore penetrate the blood brain-barrier before E.E G changes occur Since increased concentrations of calcium are known to decrease the frequency of impulses discharged from nerve cells, it is unlikely that hypercalcæmia alone could have caused the fit, but rather the serum calcium levels seem to be a measure of the toxic substance

Toxic symptoms are always associated with an increase in the diffusible (but not the ionised) calcium • This increase in the diffusible calcium seems to be due to the presence of a steroid complex to which calcium is linked Possibly this substance is responsible for toxic symptoms (Anning 1949), it has been crystallised by Dawson and Holdsworth (1949)

SUMMARY

A young man had epileptiform fits while taking calciferol 150,000 units daily by mouth for nine and a half months

Full clinical recovery took place Some slight impairment of renal function was present seven months after cessation of treatment

Electro encephalography suggested diffuse toxic effects in the cerebral cortex

We wish to thank Dr Ivan H McCaw and Dr R S Allison for encouragement, and the former for permission to publish details of this case

ADDENDUM

Since this article was written a further case has been seen by us

A woman, aged 20, was admitted to the Royal Victoria Hospital, Belfast, on Feb 21, 1951, in status epilepticus. Twelve convulsions had been observed over a period of a few hours, and the fits were rapidly controlled by intramuscular injections of paraldehyde Later it transpired that she had been treated by her doctor for Bazin's disease with sterogyl 600,000 units orally on Feb 14 and again on the day of admission During the week before admission she had been vomiting, and complaining of pain in the jaws and colicky abdominal pain, which continued for two weeks in hospital.

The blood calcium (Feb 22) was 14 mg per 100 ml. The E E G (Feb 23) was generally abnormal with diffuse slow activity, although the patient showed only slight clouding of consciousness and emotional lability, nothing abnormal was found on neurological examination, the planter reflexes being by this time flexor The trace of albuminuria cleared up on the day after admission, the blood pressure was 110/70 mm Hg, and the blood urea 30 mg per 100 ml.

Two weeks later (March 8) the E E G had improved considerably but was still abnormal, and the blood calcium was 13 mg per 100 ml No cause except calciferol intoxication was found for the fits There was no previous history of epilepsy and all other investigations were negative The patient s mother suffers from epilepsy

We wish to thank Dr J T Lewis for permission to publish the details of this case

HYPERCALCÆMIC URÆMIA WITH NEPHROCALCINOSIS DUE TO CARCINOMATOSIS

R M Fulton
M B Edin., M.R C.P E., M.R C.P
MEDICAL REGISTRAR

G E Paget
M B Durh, D C.H
RESIDENT CLINICAL PATHOLOGIST

CRUMPSALL HOSPITAL, MANCHESTER

THIS case is reported because, having correctly diagnosed hypercalcæmic uræmia, we wrongly attributed it to hyperparathyroidism The cause of the hypercalcæmia was widespread secondary carcinomatosis of bone So far as we can discover, this is the first case of its kind to be reported

CASE RECORD

On Jan 14, 1949, a general labourer, aged 25, who had been working until a week before, was admitted to hospital with a fortnight s history of constant low back pain, which radiated to his legs and was unrelieved by treatment Throughout this time he had felt weak and lethargic, his appetite had been poor, and he had vomited twice During the previous year he had lost over a stone in weight He did not complain of urinary disturbance, but had had nocturnal frequency and polyuria for three months He had no symptoms referable to the respiratory, cardiovascular, or central nervous systems.

In September, 1947, he had been admitted to this hospital with acute abdominal pain and rigidity without previous history of dyspepsia At operation a perforated gastric ulcer had been found high up on the lesser curvature with some surrounding induration This was closed he made a good recovery and he had had only occasional slight dyspepsia since There was no previous history of urinary trouble, nor anything relevant in his family history

Thus, while these unicellular sebaceous glands seem to be scattered over the epidermis generally, they are particularly important in the palm of the hand, the sole of the foot, and inner side of the eyelid

EXCRETION OF THE METHONIUM COMPOUNDS

G E Milne
M.A , B.M Oxfd, M R C P

Samuel Oleesky
M B , B Sc Manc , M R C.P

From the Department of Medicine, University of Manchester

The treatment of hypertension with methonium compounds is not free from danger, and before they can be generally used it is important to know how they are excreted or detoxicated Zaimis (1950) has developed a chemical method for the estimation of the methonium compounds and has shown that in rabbits 60–70% of an intravenous dose of hexamethonium di iodide is excreted unchanged in the urine

We have studied the excretion of hexamethonium compounds in man, and our results (table I) show that in people with normal renal function most of an intramuscular dose is excreted in the urine

After an oral dose of hexamethonium dibromide, urinary excretion is very low Our results (table II) show that much of the dose is not absorbed, and that some of this can be recovered from the fæces Absorption from the alimentary tract varies widely in the same person

TABLE I—URINARY EXCRETION OF HEXAMETHONIUM DI BROMIDE (OR IODIDE) GIVEN BY INTRAMUSCULAR INJECTION

Subject	Daily dose injected (mg)	Urinary excretion (mg per day)	% excretion
1 (Normal)	95	99	104
	50	43	86
2 (Normal)	100	100	100
3 (Hypertensive)	55	60	109
4 (Normal)	50	37	74

All these subjects had normal renal function

Certain conclusions can be drawn from these findings (1) Any of the drug absorbed from an intramuscular depot, and probably from the bowel, is excreted quantitatively in the urine There seem to be no important destructive agents in the body (2) In renal failure the drug sometimes accumulates in the blood This was well shown by one of our patients who was uræmic (blood urea 86 mg per 100 ml.) and who, on an oral dosage of 1 5 g per day, developed severe hypotension resistant to 'Methedrine' The hypotension probably lowered the filtration rate so much that further excretion of the drug was impaired and a vicious cycle developed She died of uræmia (blood urea 250 mg per 100 ml.) and still hypotensive Thus the use of the drug in patients with poor renal function is dangerous (3) Because of poor absorption from the bowel, large oral doses must be given to have any effect, but the variability of absorption makes this method of administration difficult to control. The actual amount absorbed per day when the drug is taken by mouth can be estimated from the amount present in a 24 hour specimen of urine Destruction in the bowel may actually take place but gastric juice and trypsin do not affect the compounds

TABLE II—URINARY EXCRETION OF HEXAMETHONIUM DI BROMIDE GIVEN BY MOUTH

Subject	Daily dose (g)	Urinary excretion (mg per day)	% excreted in urine
1 (Normal)	1 5	34	2 3
3 (Hypertensive normal renal function)	1 0	26	2 6
	1 0	42	4 2
	1 0	54	5 4
	2 0	105	5 3
	2 0	185	9 3
	3 0	300	10 0
	4 0	520	13 0
5 (Hypertensive urea clearance 67 % albuminuria)	3 0	227	7 6
	3 0	324	10 8
	3 0	385	12 8
	3 0	437	14 6
	3 0	307	10 2
	3 0	176	5 9
	3 0	121	4 0
	3 0	139	4 6

In case 3 the fæcal excretion was measured on three occasions and found to represent 19–30 % of the daily dose

Thanks are due to Prof R Platt for permission to report these findings and for help in this study

STREPTOMYCIN IN LETTERER-SIWE'S DISEASE *

R P Aronson
M B Lond , M.R C.P , D C.H

SENIOR PÆDIATRIC REGISTRAR, FARNBOROUGH HOSPITAL, KENT

Letterer (1924) was the first to describe, in a child aged 6 months, a disease characterised by a purpuric rash, enlarged lymph glands, an enlarged spleen, and invasion of the spleen, liver, and bone marrow by endothelial cells Siwe (1933) reviewed Letterer's cases and added his own, and Abt and Denenholz (1936) published a further case

CLASSIFICATION OF RETICULOSES

Siwe (1949) classifies the reticulosis found in childhood into three main groups

1 *Lipoid reticulo endotheliosis*, of which Hand-Schüller-Christian disease, Gaucher's disease, and Niemann-Pick's disease are examples

2 *Eosinophilic granuloma*, which is a special form of the non-lipoid reticulosis occurring in one or more bones The ages of the patients have been between 11 months and 11 years (with a few cases reported in adults) There is a strong tendency for the lesions to heal within one or two years, even in the absence of treatment by curettage Biopsy of the material shows a granulomatous lesion with eosinophilia, but no foam cells are present There is no tendency for the lesions to spread

3 *Non-lipoid reticuloses*, of which Letterer Siwe's disease is one. In contrast to that of lipoid reticulosis, the onset is always acute, with generalised reactions The main features are

(*a*) A fair degree of enlargement of the liver and spleen

(*b*) A hæmorrhagic tendency which manifests itself as petechiæ or purpura

(*c*) Generalised enlargement of the lymph glands, which are discrete and not tender

(*d*) Localised tumours over bones may be noted, and cyst formations in bones have occurred

(*e*) The leucocyte count (total and differential) is normal, and there is a progressive secondary anæmia There necropsy, to Mr H V Street, who performed the biochemical investigations, and to Dr D M Macartney, medical superintendent, for permission to publish the case

---

* This disease is named after Erich Letterer and S A Siwe—not one person (Erich Letterer-Siwe), as some reference books state —Ed L

UNICELLULAR SEBACEOUS GLANDS IN THE BASAL LAYER OF THE NORMAL HUMAN EPIDERMIS

EUGENE WOLFF
M B Lond, F R C S
OPHTHALMIC SURGEON, ROYAL NORTHERN HOSPITAL, SURGEON, MOORFIELDS, WESTMINSTER AND CENTRAL EYE HOSPITAL

From the Institute of Ophthalmology, London

IT is always said that the palm of the hand and sole of the foot have no sebaceous glands, and hence presumably the skin of palm and sole is lubricated only by the sweat glands This I now believe to be incorrect

For some time I have been trying to ascertain why the flat yellowish growth known as xanthelasma palpebrarum is found 100 times more often on the inner side of the eyelids than on the skin of the whole of the rest of the body put together Apparently, contrary to all accounts of the condition, it arises as a downgrowth of very interesting cells in the basal layer of the epidermis These cells are distinguished from the other cells of this layer by the fact that they undergo changes similar to those seen in the cells in an ordinary sebaceous gland the nucleus swells, becomes rounded, stains paler, and usually contains one well marked nucleolus, later still it becomes very dark The protoplasm is converted into a network and stains with Scharlach R

Obviously the next step was to see whether these cells were present in the normal epidermis Figs 1–3 illustrate sections of normal skin removed (at operation) from the inner side of the upper eyelid and fixed in 10% formalin Fig 1, from a section embedded in paraffin and stained with Masson's stain, shows how numerous are the special cells here described, fig 2, from the same section under higher power, shows the typical changes in the nucleus and protoplasm, and fig 3, from a frozen section stained with Scharlach R, shows the fat in the basal cells which is stained red The basal cells are birefringent with polarised light and stain purplish with the Liebermann Burchardt reagent (acetic and sulphuric acids) and grey with osmic acid There can be no reasonable doubt then that they are unicellular sebaceous glands

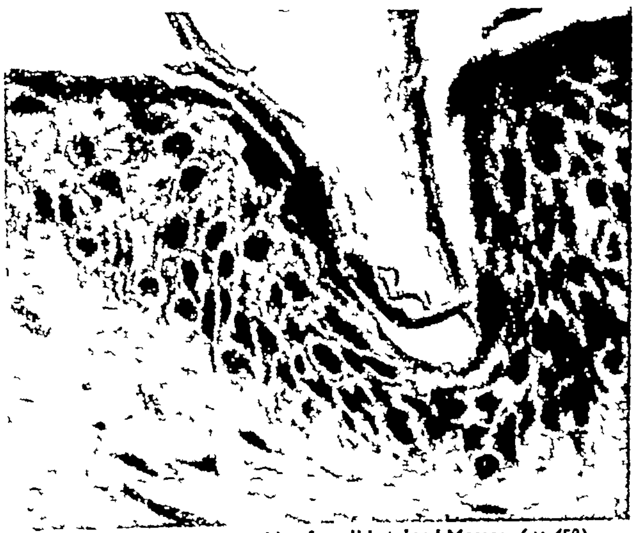

Fig 1—Skin from inner side of eyelid stained Masson (× 450)

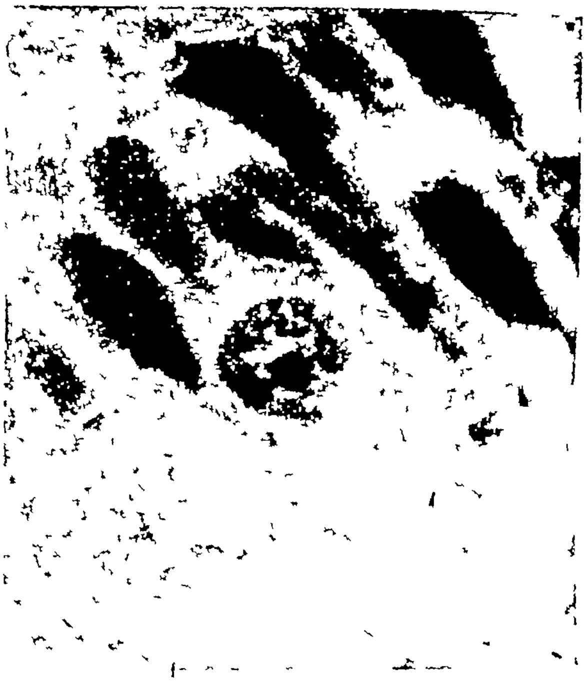

Fig 2—As fig 1 (× 2650)

That sebum forming cells should occur in the basal layer of the epidermis is not really surprising, when we remember that sebaceous glands themselves develop as a downgrowth of this layer These cells are the same as those described by Masson (1926) as *cellules claires* he thought they were derived from Schwann cells and were important in the development of the melanomata

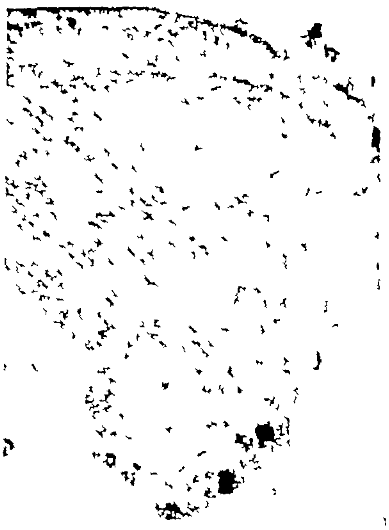

Fig 3—Frozen section stained with Scharlach R (× 532)

A further examination of the skin from the inner side of the eyelid shows that the few hairs it contains are mostly feeble and have only rudimentary sebaceous glands attached to them, or none at all Probably, then, the numerous unicellular sebaceous glands in the region are there to take the place of ordinary sebaceous glands And the same would no doubt apply to the palm of the hand and sole of the foot, where the ordinary sebaceous glands are absent

Preliminary Communication

EFFECT OF CORTISONE ON PNEUMOCOCCAL BACTERÆMIA

Harvey Cushing,[1] in his classical account of pituitary basophilism, remarked that "the malady appears to leave the patients with a definite susceptibility to infections" Death in the nine fatal cases described was ascribable to, or associated with, multiple cutaneous abscesses and ulcers, intercurrent erysipelas, acute pulmonary complications, intercurrent meningitis, streptococcal phlegmon, and pancreatic necrosis Crooke[2] states that in basophilism "death usually comes rapidly as a result of infection following some trivial injury or manipulation" Kass et al,[3] in a study of the effects of adrenocorticotropic hormone (ACTH) in pneumonia, record a case due to pneumococcus type 8 in which the institution of therapy was followed by bacteræmia which persisted after the clinical crisis

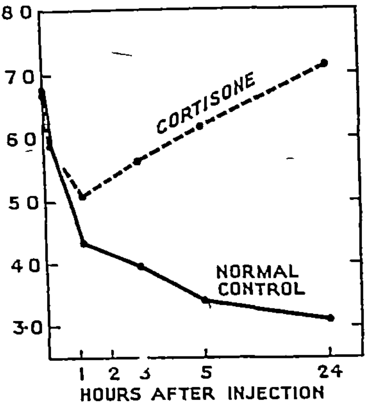

Fig 1—Results in experiment 1

The following experiments were planned as part of a general investigation of the influence of 'Cortisone' on phagocytosis These preliminary findings are presented in order to emphasise one of the possible dangers involved in cortisone therapy

A 24 hour culture of the pneumococcus was used as the test organism Throughout the experiments we adhered strictly to this culture period, in view of the reported influence of the state of encapsulation of the pneumococcus on the course of the initial bacteræmia after intravenous injection of this organism[4] Each experiment was made with a pair of male rabbits of approximately equal weight, maintained under identical conditions of housing and diet One animal served as a control The other received intramuscular injections of a saline suspension of cortisone acetate (Merck), as follows

Relation to injection of pneumococci (hours)	*Dose (mg)*
− 20	20
− 1	15
+ 24	15
+ 48	15

At zero time 1 ml of culture was injected by an ear vein At varying intervals thereafter, 1 ml of blood was withdrawn by syringe from the opposite ear and immediately expelled into nutrient broth containing 0·2% sodium citrate and 0·1% white saponin (B.D.H.) The number of organisms in the blood sample was estimated by the pour plate technique, several dilutions were prepared in saponin citrate broth, and the final concentration of rabbit blood in the poured plate was adjusted by the addition of the calculated amount of sterile fresh rabbit-blood. Plates were incubated at 37°C for 48 hours and then counted, after choosing the dilution showing colonies in the range 100–1000 The blood content of pneumococci immediately after injection was calculated from the content of organisms in the 24-hour culture and from the blood volume, taken as 5% of the body weight

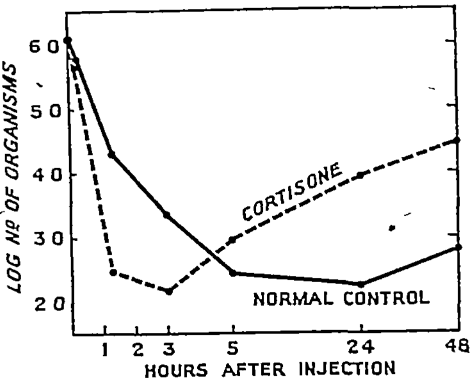

Fig 2—Results in experiment 2

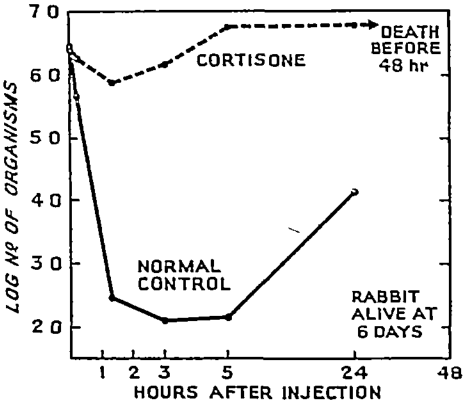

Fig 3—Results in experiment 3

The weights (g) of the control and treated animals in each of the experiments were as follows expt 1, 2150 and 1750, expt. 2, 1750 and 1650 expt. 3 2150 and 1900 expt 4 2200 and 1800

Expt 1—Observation continued 24 hours when both animals were sacrificed for histological examination
Expt 2—Observation continued 48 hours when both animals were sacrificed for histological examination
Expt 3—Observation continued 5 days when control animal was still alive and well Treated animal was found dead at 48 hours.
Expt 4—Observation continued 6 days when control animal was still alive and well Treated animal was found dead at 24 hours

are non lipoid containing macrophages in the spleen and other affected organs

(*f*) The disease is seen only in infants, and ends fatally It is neither hereditary nor familial

(*g*) There is a generalised hyperplasia of the macrophages present in the spleen and other affected organs These cells are large, round (sometimes polygonal), and pale staining, they do not contain lipoid, occasionally multinucleated giant cells are seen, and there is an increase in the reticular fibres The organs that may be affected are the spleen, liver, lymph glands, bones, lungs, skin, thymus, and lymph follicles of the intestine The presence of the enlarged macrophages may cause distortion of the normal architecture of the lymph-glands and spleen, areas of necrosis and hæmorrhages may occur

The case described below seems to fulfil the criteria first laid down by Siwe, although in addition this child had a hæmolytic anæmia, and, unlike all previous cases described, seems to be recovering She is alive and apparently in perfect health more than two years after the onset

Siwe (1933) did not suggest that all the cases he described were due to the same cause Some he regarded as due to infection, but this as a cause has been excluded as far as possible in the case described here

CASE RECORD

A girl, aged 18 months, was admitted to the Leicester Royal Infirmary on Jan 13, 1949 During the past month her mother had noticed that she was becoming paler, was refusing her feeds, and was irritable and fretful Also her urine had been darker than normal The child's birth weight was 7 lb 8 oz, and after being breast fed for a month she had been reared on National Dried Milk Her weight was 22 lb 4 oz She was an only child, both her parents were in good health, and there had been no known contact with tuberculosis or other infectious illnesses She had had no previous illnesses

On examination the infant was a blonde blue eyed baby She had a striking degree of pallor but did not appear jaundiced Very irritable, she keenly resented examination There were scattered petechiæ and purpuric spots all over her body, but chiefly on the trunk Her tonsils appeared healthy, and her tongue furred. There was a mucopurulent discharge from both nostrils Cervical glands were moderately enlarged on both sides, the left tonsillar gland being particularly large It was smooth, soft, not adherent to the overlying skin, and not tender Nothing abnormal was found in the lungs A soft systolic murmur was heard at the apex of the heart The blood pressure was 100/60 mm Hg The liver was palpable one finger breadth below the costal margin The spleen was much enlarged, the angle of the spleen extending to the level of the umbilicus The spleen was smooth and firm and did not seem to be tender The inguinal glands were slightly enlarged *B coli* were present in the urine There was remittant fever ranging between 100° and 103°F and tending to be highest at night

Examination of the blood and bone marrow confirmed that hæmolytic anæmia was present, with Hb 57% The bone marrow was hyperplastic, with large numbers of extremely immature red cells There was some delay in maturation of the leucocytes

Operation —Owing to the rapid rate of hæmolysis a trans fusion (1 pint) was given, but the patient continued to hæmo lyse her blood and became slightly jaundiced On Feb 13, a further transfusion was given in preparation for splenectomy This operation was performed (Feb 15) because of the pro nounced hæmolytic anæmia and because hypersplenism was suspected After splenectomy the hæmolytic process seemed to be arrested, and regeneration of the blood began slowly However, the evening pyrexia was unaltered, the petechiæ continued to appear in crops, the glands in the neck remained enlarged, and the patient remained fretful

The *spleen* was found to be enlarged, with areas of thickened peritoneum covering it Sections were stained with hæma toxylin and eosin for reticulin, and by Scharlach red, Sudan black, and Nile blue sulphate, and by Schultz test for cholesterol Scattered throughout the medulla were focal collections of large endothelial cells which appeared to be compressed at the periphery and were surrounded by fibroblastic rings The malpighian corpuscles seemed to be compressed and were relatively scanty The cells of the focal collections had a somewhat granular cytoplasm but did not appear to contain lipoid A few cells were undergoing mitosis Sections stained to show lipoid were uniformly negative There was no central necrosis, but apparently some erythrophagocytosis There were occasional giant cells of the mirror image type Though the histology suggested sarcoidosis, the lack of central necrosis and the absence of fibrillary structure were against this diagnosis, and the evidence pointed to a non lipoid reticulosis of the Letterer Siwe type

Streptomycin therapy —A preliminary examination of the spleen had suggested a diagnosis of sarcoidosis, and as sarcoidosis is thought by some to represent an atypical response to the tubercle bacillus, and the response to splenectomy had not been very dramatic it was decided to try streptomycin. The dose used was calculated as 0 02 g per lb of body weight per twenty four hours, given in two doses morning and evening Treatment was begun on Feb 24, 1949, and continued for five weeks

Seven days after streptomycin treatment started, the enlarged cervical glands were no longer palpable, the tempera ture had begun to settle, and for the first time the body was entirely free from petechiæ On March 7 the Hb was 63% A few days later the temperature had completely settled. In December, 1949, the child was still perfectly well, the hæmoglobin was 83%, the red cells numbered 4,470,000 per c mm, there were no enlarged glands, and the child was gaining weight Seen on April 26, 1950, she was a happy active normal child and a blood count showed red cells 4,520,000 per c.mm, Hb 84%, colour index 0·93, and white cells 11,100 per c mm (polymorphs 51%, lymphocytes 47%, monocytes 2%)

DISCUSSION

This case presented as hæmolytic anæmia but was otherwise typical of the condition described by Letterer and later reviewed by Siwe The diagnosis was not made until histological examination of the spleen had been completed Splenectomy did appear to arrest the hæmolytic process, but otherwise the child's condition was not greatly altered The response to strepto mycin, on the other hand, was remarkable the enlarged cervical glands at once began to diminish, and all the other physical signs and symptoms disappeared

The child has remained well now for over two years. All the previous cases reported have progressively deteriorated, the longest survival being two years.

Though the ætiology of Letterer Siwe's disease is unknown, Siwe has suggested that various kinds of sepsis or reactions to as yet undetermined toxins may be factors The *favourable* response to streptomycin lends some support to this idea Of course, the possi bility of a spontaneous remission cannot be ruled out, but remissions are not a feature of the disease

Acknowledgments and thanks are due to Dr Vernon Braithwaite for permission to publish this case, Dr E. Milford Ward, for the pathological report on the spleen, and Dr H S Baar for confirming that the histological appearances of the spleen were those of Letterer Siwe's disease

' In my academic pursuits in three universities, I associated with some *learned* men who professed to believe that scholarly achievement is accomplished *only* under the stress of monetary insufficiency—that the church mouse graduate student or fellow invariably out-performs the student with ample funds This is a ridiculous assertion. Many fine minds have been lost by the world of scholarship because its monetary rewards are so poor I personally believe much excellent work has been done *despite* penury and not because of it —Prof DONALD BAUER, of Wisconsin, in *Science*, 1951, 113, 331

Mr Brock went on to talk of mitral stenosis, saying that this was a much more important subject, since only 2% of heart disease was congenital whereas 25% was of rheumatic origin, the condition was, in fact, a national problem The anteromedial cusp of the mitral valve might be said to form the intraventricular part of the aorta, and it must on no account be damaged or split At operation the commissures were split with the finger, the valve was not merely *dilated.* He thought that the best age for operation was between 20 and 40, the oldest patient was aged 50 Fibrillation and embolism were not contra indications, nor was calcification of the valve, which was present in almost half of his series He had so far performed 48 of these operations, 8 patients had died, but all of the last 24 had survived

Dr **Maurice Campbell** observed that the indications for mitral valvulotomy were not clear cut, so far cases had been selected conservatively, only the bad cases being accepted. The operation was chiefly of value where the disorder was essentially mechanical, and this could be expected when the main symptoms were orthopnœa, cardiac asthma and pulmonary œdema, and perhaps recurrent hæmoptysis The main contra-indication was active infection or the chance of this recurring, and for this reason patients under 20 were rarely suitable Slight aortic incompetence or mitral regurgitation should not prevent a good result, but a greater degree of these changes was likely to do so Patients with long standing congestive failure had passed the stage when they could best be helped So far the results had been surprisingly good, even pulmonary hypertension had decreased considerably

In patients with coarctation he found great difficulty in deciding whether to advise operation, many were able to lead a normal life and kept well for so long that an operative mortality of 10% with another 10% who could not have an anastomosis done (Gross 1950) was not a justifiable risk unless there were signs that the patient was not doing well

In patent ductus the risk was already much less, and when it was reduced to 1% (as it was in the hands of Professor Crafoord) nearly all cases should be advised to avail themselves of the chance of cure He felt, however, that despite the 10% mortality which might be associated with operations for Fallot's tetralogy this was well justified by the 80% good results, since without operation the outlook was poor He concluded that so far valvulotomy had proved it could produce as successful results as Blalock's operation, though he was not quite sure whether it succeeded in quite so high a proportion of cases Like Mr Brock, he was doubtful about the results of direct operation for infundibular stenosis, although this had started so well

Reviews of Books

Pharmacology of the Failing Human Heart

John McMichael, M D, F.R.C P, professor of medicine in the University of London at the Postgraduate Medical School of London Oxford *Blackwell Scientific Publications* 1950 Pp 63 8*s* 6*d*

The introduction of cardiac catheterisation and its establishment as a safe method of investigation has been a great stimulus to the study of the circulation In the early days of any new technique, misleading conclusions are apt to be drawn from insufficient data at this stage observation is more important than interpretation, and working hypotheses may have to be modified to fit in with new facts Professor McMichael's monograph—one of the American Lecture Series—is not so much a guide to treatment as a very able account of the hæmodynamics of cardiac failure and an explanation of how established remedies may work His review is based largely on his own work and on personal discussions with other leaders in this field, and there are generous references to published work The concept of high and low output failure is restated, Starling's law of the heart reconsidered, and the importance of the myocardium emphasised A full discussion of the mechanism of cardiac failure precedes a particular account of the action of mercurial diuretics, and of digitalis and its allies, and the management of individual therapeutic problems is discussed No doubt there are good reasons for the success or failure of digitalis in certain types of patient, but we remain in fundamental ignorance of its ultimate mode of action Many with long clinical experience and knowledge of earlier experimental work will be relieved to learn that perhaps after all the primary action of digitalis is on the heart This book is authoritative and up to date, clearly expressed and well produced

Chemistry and Therapeutics of Synthetic Drugs

J W Keyser M.Sc Lond, A.R I C biochemist, department of pathology Welsh National School of Medicine London *Newnes* 1950 Pp 458 42*s*

A book which really lived up to the title of this work would be invaluable, but in attempting to provide a "reference book for medical men, pharmacists, chemists and students" the author has set himself an impossible task and has failed fully to satisfy any of his aims. There is a large amount of information, but for whom some of it is intended is not clear For instance, a page is used to describe Bratton and Marshall's method of estimation of sulphonamides, which is too much for the general medical reader yet not enough for any worker who wants to perform the examination

No doses are given, and loose terms such as "moderate" and "large" doses are used. The abbreviation *N.F* used throughout the book does not (as might be supposed) indicate the British *National Formulary*, but the American one The description of chemical synthesis varies enormously the synthesis of quinine would be understood only by an experienced organic chemist, and then with difficulty, whereas the synthesis of camphor from pinene, which is well known, is very clearly and graphically expressed If penicillin is included at all in such a work, surely the structure of the six penicillins referred to should be given, and not merely a statement that they exist

The appendix of trade names is useful but cross reference to the body of the work is difficult Thus 'Physeptone' appears in the appendix together with its chemical name, but neither physeptone nor its chemical name appears in the index, and only if the reader already knows that amidone is another synonym can he find the appropriate text page

What is Hypnosis?

Studies in Auto and Hetero Conditioning Andrew Salter London Athenaeum Press 1950 Pp 90 8*s* 6*d*

Present-day theories of the unconscious owe their origin to the study of hypnosis and this remains the most direct and striking method of psychotherapy although perhaps at the moment the least fashionable No system of psychopathology has yet produced a convincing explanation of its phenomena, although these have been re-described and re-labelled in the language of many systems The objective experiments of Clarke Hall and of Kretschmer have taken much of the mystery out of the subject While these workers have rightly claimed it as material for a wholly scientific approach they have yet hesitated to put forward a theoretical framework to embrace all its features Andrew Salter is a behaviourist who is not lacking in objectivity, he is also human enough to be alive to therapeutic possibilities He points out that hypnotic suggestion has similarities with the process of "conditioning" which produces a conditioned reflex, and feels that the elements of mastery in the hypnotist and dependence in the subject, of which so much has been made in the past, are irrelevant Like Kretschmer and Schultz he has seen the possibilities of teaching the patient to become his own hypnotist, to condition himself The descriptions of his experiments and methods of treatment will ring very true to anyone with practical experience of hypnosis, and they are easily verified in practice In his methods of autohypnosis the author

The results are shown in the accompanying table and in figs 1–4, each representing an experiment with a pair of animals, in each pair the same culture was injected at an interval of 10 minutes, and both animals were followed concurrently

The results agree in demonstrating a striking difference between the course of the bacteræmia in the cortisone treated and in the normal animals In experiments 1 and 2 the number of organisms fell initially in both groups of animals In experiments 3 and 4 this initial fall was slight or absent in the case of the cortisone treated animals At the 3rd hour in experiments 1 and 2, and even earlier in experiments 3 and 4, the number of organisms in the cortisone treated animals began to rise, while in the normal controls the number continued to fall, thereafter, the number of organisms in the cortisone treated group increased rapidly resulting in death within 48 hours in experiment 3, and within 24 hours in experiment 4

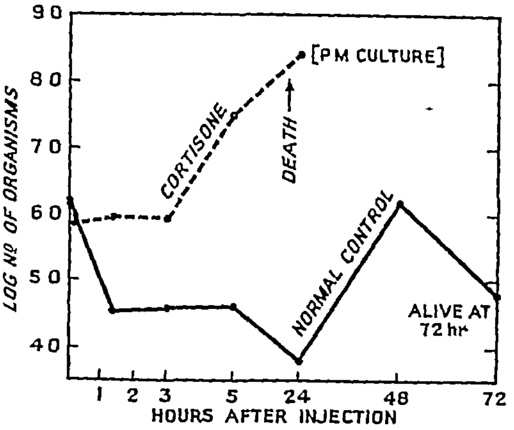

Fig 4—Results in experiment 4.

It would be premature to speculate in detail on the cause of this disastrous effect of cortisone on the course of pneumococcal bacteræmia We are at present engaged in a survey of the effects of cortisone on phagocytosis of bacteria and inert particles, and the results with organisms other than the pneumococcus must not be anticipated In the case of inert particles, Selye[5] has claimed that A C T H markedly increases the phagocytosis of indian ink As regards other bacterial infections, D'Arcy Hart and Rees[6] described an enhancing effect of cortisone on tuberculosis in the mouse, but it is difficult to correlate this with the present work

Cortisone might well be expected to have a deleterious effect on the course of an infective process, in the light of the observation by Bjørneboe et al[7] that antibody production in the rabbit decreases under the influence of cortisone and A C T H But the effects noted by us are demonstrable too early to be attributed to this mechanism Further, the action of cortisone in inhibiting granuloma formation or mitotic division of cells can hardly be relevant, since the clearance of organisms from the blood stream at this early stage of an infection must depend on the already differentiated phagocytes

We are indebted to the Medical Research Council s committee on A C T H, cortisone, and related substances for supplying the cortisone, and to Prof S P Bedson and Prof Dorothy Russell for helpful criticism and encouragement

Medical Societies

ROYAL SOCIETY OF MEDICINE

Surgery of the Heart and Great Vessels

THE surgical section of the Royal Society of Medicine met on April 4, under the chairmanship of Sir STANFORD CADE, president of the section, to discuss the surgery of the heart and great vessels

Prof C CRAFOORD dealt chiefly with patent ductus arteriosus and coarctation of the aorta, both of which, he said, though of doubtful ætiology, were essentially due to too little or too much connective tissue reaction after birth at the site of the ligamentum arteriosum Coarctation of the aorta was found once in 7000 births, and 90% of the patients died before the age of 50, mostly through cardiovascular accidents Symptoms started sometimes as early as the age of 5 years, and nearly all patients had symptoms by the age of 25 Some complained of hypotensive effects in the lower limbs, and in many the mental and physical powers were greatly increased by operation The prognosis was unpredictable, and sudden death sometimes took place from acute cardiac failure In most of his 85 cases excision of the stricture with an end to end anastomosis had been performed, and subsequent angiocardiography showed that a lumen which was 60% of normal was adequate Already 24 of his patients were well and at work, 5 years after operation, 17 of these were symptom free As to the age for operation, the limiting factor was arteriosclerosis, he had seen this developing as early as $3^1/_2$ years and as late as 43 years The upper age limit for surgery seemed to be 30 years, but the sooner the patient was operated on, the better

Turning to patent ductus arteriosus, Professor Crafoord said that he had had 282 cases, 16 of which were atypical in that a large right heart and pulmonary hypertension were found Of these 16 patients 8 had died after operation, whereas of the remaining 266 only 2 had succumbed He felt that morbidity and mortality were undoubtedly higher in patients who were not subjected to operation than in those who were operated on, and 90% of the patients were actually better for the operation The optimum time for surgery was at ages between 3 and 12 years When the duct was long enough for a 2 mm gap to be left between the ligatures, the operation of choice was double ligature, failing this, division and suture should be undertaken In all, 4 cases of his had recanalised

Mr R C BROCK said that the surgical approach to heart disease could now be either direct or indirect, and he confined his remarks largely to the former He had performed, in all, 130 intracardiac operations for pulmonary and mitral stenosis The results of the Blalock operation were excellent, and the mortality was low, but the essential lesion—pulmonary or infundibular stenosis—remained and might increase, and thus a direct attack was at least theoretically preferable He was sure that for pure pulmonary stenosis valvulotomy was essential, and here Blalock's operation was absolutely contra indicated He also felt that valvulotomy was the correct procedure for patients with a valvular stenosis in Fallot's tetralogy, but he was as yet less certain that the infundibular punch which he had designed for the treatment of infundibular stenosis, gave as good results as did Blalock's operation He had performed 57 pulmonary valvulotomies with 10 deaths—28 for pure pulmonary valvular stenosis, 29 for Fallot's tetralogy There had been only 1 death in the last 29 cases Infundibular resection had been done in 22 cases with 7 deaths, combined infundibular resection and valvulotomy in 6 cases with no deaths

THE LANCET
LONDON SATURDAY, APRIL 21, 1951

Sisters or Daughters?

A CHIROPODIST writing to us the other day described herself as a member of a junior branch of the medical profession, and complained of a surgeon's action as unseemly in a colleague of the senior branch. What then *is* the medical profession? "The distinction between work which requires and work which does not require a medical qualification is blurred," writes Dr FFRANGCON ROBERTS[1], for we have not only allowed but even initiated and encouraged the dilution of our labour. Clearly, the medical profession proper consists of people who have gone through a full course of training in a medical school—a course intended to fit them not only for the diagnosis and understanding of disease but for the care and understanding of patients. The position of a physicist or biochemist working in medicine is equally plain: he is an honoured colleague from a sister profession making his own contribution to medicine on equal terms. But what about the physiotherapist, the almoner, the dietitian, and the speech therapist? Are they members of sister professions, or are they daughter members of our own? Ought we, perhaps, to enlarge our conception of the Greater Medical Profession to embrace everyone who works in a medical organisation such as the National Health Service? This question arises from the report of the Cope Committees summarised on another page.

We can fairly begin by excluding from professional status a proportion of those who work in the N.H.S.—porters and wardmaids for example. Professionalism is nowadays extending rapidly: hairdressers have been trying to establish a State register for themselves, and any dignified vocation, such as that of butler, tends to describe itself as professional. But, though times change and we with them, it is probably still correct to say, with CARR SAUNDERS and WILSON[2] that no calling is truly a profession which does not require a long specialised intellectual training in its technique. In the typical profession this technique is derived from a basic field of inquiry, and CARR-SAUNDERS and WILSON illustrate this by saying that doctors and dentists are concerned with science whereas nurses and midwives are concerned only with the application of science. But they add that the more the practice of a technique is likely to arouse a sense of personal responsibility, and create a direct and personal relation with clients, the closer will be the approach of a vocation to a profession; and here not only the nurse and midwife have a strong claim, but also many of the other groups who take on part of the care of the patient—the occupational therapist, the almoner, the physiotherapist, and the dietitian. The laboratory assistant in the hospital, or the pharmacist, will see patients less often; but the welfare of these patients may nevertheless depend on his responsible performance of a specialised technique acquired only by years of training. In all these activities the desire for professional status has led to steadily rising standards, both technical and ethical; which is mainly to the good. But Dr ROBERTS paints a dismaying picture of a medical service in which the doctor will hardly get a word in edgeways; and in a letter we publish this week Dr RABSON makes the still more painful suggestion that the doctor's claim to be a doctor, different from the other technicians, has less and less foundation.

The Cope Committees excluded nursing from their purview because nurses already have their own registration councils; but they deal with eight other groups of non-medical staff working in the N.H.S.—almoners, chiropodists, dietitians, medical laboratory technicians, occupational therapists, physiotherapists, radiographers, and speech therapists. Their main report, which is endorsed by the medical members of every committee, accepts the term "medical auxiliaries" for all these diverse callings, pointing out that they all "work for the benefit of the patient under the direct or indirect supervision of the doctor." This conception leads naturally to the proposal that the training and registration of the various groups should be entrusted to a statutory council whose members would be mostly *medical*, and that the professional committee charged with the affairs of each group should be the agents of the main council. The scheme suggested is workable and has conspicuous advantages; but it is based on the idea that the callings in question are junior, ancillary, branches of medicine, which need to be developed paternally as part of the whole. This idea is vigorously challenged in a minority report by two almoners, two occupational therapists, and a speech therapist. They object to the term "medical auxiliary" in relation to their professions; for a profession is a calling having its own standards of training, principles of practice, and professional ethic. They believe that the majority proposals would undermine the sense of responsibility within the professions concerned, and they cannot believe that the Government will accept recommendations which would deny to any profession full responsibility for establishing and maintaining its own standards.

> "We consider that the establishment of a central controlling Council to direct a number of distinct professions, whose diversity is clearly apparent, could only have a stultifying effect on the work of the professions concerned. . . . The recommendations . . . are based on the assumption that doctors can, by virtue of their medical training and experience, satisfactorily plan and control the curricula of training and methods of work of the professions under review. From our experience this is not in accordance with the facts. We agree that members of our professions must work closely with the other specialists in the team treating the patient, of which team the Doctor is the undisputed leader. This, however, presupposes a very different basis of association from that which the Report assumes. Almoners, being primarily social workers, bring into the health services knowledge and experience learned in the social science departments of universities and in fields of social service other than health. Occupational Therapists and Speech Therapists also offer specialised knowledge and skills which can only be acquired outside the field of medicine."

Instead of the single registration council favoured by the majority, this minority propose that each profession should have its own registration board, a small central council being set up, if need be, to advise offers something for the patient who is too proud to surrender all his thoughts to a psycho-analyst or who has at the outset too little hope or leisure to settle down to a prolonged transference relationship The book is short and the author's enthusiasm makes it very readable It is much improved by a foreword by E B Strauss which brings it into relationship with other recent work on the subject of which the author was unaware at the time of writing At a time when the therapeutic efficacy of abreactive methods based on the elastic theories of psycho analysis is much in question, this book may well play its part in the swing of psychotherapeutic fashion towards less interpretative methods The writer has made a good case for regarding the phenomena of conditioning as at least as important as those of transference

Recent Advances in Ocular Prosthesis

J H PRINCE, F B O A, F S M C, F R M S, F Z S Edinburgh E & S Livingstone 1950 Pp 156 20s

THIS book is the companion volume of *Ocular Prosthesis* by the same author, and is timely in view of the use of acrylic in the manufacture of the "ocular prosthesis," and the interest aroused by recent work on implants of tantalum and 'Vitallium,' which can be fixed into Tenon s capsule by suturing the rectus muscles and the attachment of the acrylic prosthesis to the implant These advances improve both the comfort and appearance of those who suffer the misfortune of losing an eye Mr Prince gives good descriptions of the technique of making conjunctival impressions, of the chemical and physical properties of methyl-methacrylate, of 8 methods of making an artificial iris, and of the fabrication and processing of acrylic prostheses The illustrations, too, are good It is unfortunate that he has not taken proper advice about anatomical terms, and about some facts in the surgical operation which he has tried to describe, for there are several mistakes and inaccuracies Thus recession of the upper lid is not due to the pull of the superior rectus, but more probably to the downward displacement of orbital fat, and his suggestion that animal conjunctiva might be used to graft a contracted socket shows him to be unaware of the fate of such grafts, and of the reaction of the host to foreign protein Again, no competent surgeon would rob an eyelid of skin to line part of a socket The term orbital cavity is used several times when conjunctival sac is intended For those engaged in making ocular prostheses, however, the book will prove highly valuable

Modern Trends in Neurology

Editor ANTHONY FEILING, M D, F.R C P, senior physician neurological department, St George's Hospital London Butterworth 1951 Pp 717 63s

THREE of the twenty articles in this volume are by workers in the United States D E Denny-Brown contributes an exhaustive and admirable account of the physiology and clinical aspects of frontal lobe function, E C Kunkle and H G Wolff give an account of headache based on their experiments, and W J Mixter writes on rupture of the intervertebral disc This last article emphasises the importance of myelography in diagnosis, an investigation largely discarded in this country in the diagnosis of disc protrusions Among the sections by British authors are an outstanding discussion on the conduction of the nervous impulse by W A. H Rushton, a detailed study of intracranial aneurysms by S P Meadows, and a stimulating account of cervical rib and axillary inlet compression syndromes by F M R Walshe In addition to the physiological and clinical articles, radiology of the nervous system is lucidly described by J W D Bull, and Denis Williams discusses the clinical applications of electro-encephalography It is somewhat surprising that there is no section on the nutritional and metabolic aspects of neurological disease, or on the experimental work on the production of demyelination—subjects which have seen definite advances in knowledge in the last few years The production of the book, and the clinical and pathological illustrations and X ray reproductions, are of a very high standard, but there are some inaccuracies among the references We congratulate Dr Feiling on his editing of a valuable book

Human Embryology for Medical Students

S R NAIR, department of embryology, Topiwala National Medical College, Bombay Bombay Popular Book Depot 1950 Pp 364 £2 2s

Dr Nair intends his book to serve as a "handy reference" rather than as a textbook of embryology, and it is in fact considerably shorter than most such works Since he covers the usual topics of human embryology, the brevity has been attained by describing in less detail the various developmental processes, and sometimes this tends towards obscurity For example it is unlikely that the student will understand the development of the heart from the description given, unless he supplements it from other sources There are a large number of illustrations, most of them drawings, and all in line generally they are clear and accurate, but their relevance would have been more evident if they had been mentioned in the text On the whole this book will be of more value read as a supplement to lectures than as a textbook in its own right Several existing textbooks are more richly illustrated at a lower cost

Metabolic Interrelations

(Transactions of the Second Conference) January 9-10, 1950 New York Josiah Macy, Jr, Foundation. 1950. Pp 279 $3 95

THE first of these conferences on metabolic interrelations, held in February, 1949, was devoted largely to the biochemistry of bone This second conference was held about a year later, and, since all the papers were about bone, the name "Metabolic Interrelations" is a little misleading The report follows the lines of its predecessor There were eleven papers, some of them frankly physicochemical, such as those on the composition and structure of the bone salt, or on bone as a problem in surface chemistry, others were more biochemical, dealing with the enzymic activity of bone or the effect of hormones and vitamins on its metabolism and calcification A few —such as the one on strontium as an adjuvant to calcium in the remineralisation of the skeleton in osteoporosis in man—were based upon a study of clinical material. They are all rather highly specialised, but none the less interesting to workers in the field of bone metabolism. Sometimes the reports of the discussions exceed the length of the papers themselves, and they are not always very illuminating A little work in the editorial department of the Josiah Macy Foundation would enhance the appeal of their reports

Catalogue of Lewis's Medical, Scientific & Technical Library (London H K Lewis 1950 Pp 1152 35s)—This catalogue has now been revised to Dec 31, 1949, and readers and librarians alike will be glad to have this new edition for reference The familiar red volume, a little stouter than of old now contains about 27,000 titles In the introduction to the classified index of subjects, there is a mild editorial complaint that this work has been made more difficult by the uninformative and misleading titles which are nowadays often given to 'otherwise serious works" To help the would be reader the initials of authors and the year of publication have been inserted in this part of the catalogue, and a word or two has often been added to show the nature and scope of the book.

Medizinische Psychologie (10th ed Stuttgart Thieme, 1950 Pp 304 D M 24)—This stimulating compendium of Prof Ernst Kretschmer s studies and opinions provides a coherent introduction to psychiatry, but ignores such vast tracts of other men's work that it can hardly be called up to date Professor Kretschmer leans strongly towards the attribution of psychological happenings to cerebral areas, in the manner of Kleist of Frankfurt, and includes in this edition many details of W R Hess s work on vegetative centres in the midbrain. But in this and in his references to the orbital region and its functions he is evidently unaware of the many investigations made in the English speaking countries, nor does he quote French investigators in relevant fields In the main the book remains a vigorous exposition of German medical psychology in its most progressive form unded of other components of the United Nations 'ce, there is no reason to suspect any inadequacy today In comparing the organisation of medicine in Korea th the organisation to which many of us became customed in the late war, the biggest stumbling-ock is terminology A mobile surgical hospital ipears to correspond to a C C S with several attached rgical units , but the range of function of separate abulance company, separate collecting company, id separate clearing company is difficult to calibrate y the measure of our field ambulance and mobile nbulance column If the employment of armies rawn from many nations becomes common practice iere will no doubt be attempts to introduce some niformity in these things Names matter very little, id we would suggest that the hallmark of an efficient eld medical organisation is intelligent training irected to individual responsibility in small units nd to elasticity sufficient to cope with changes in errain and great fluctuations in the number of wounded Most of the catastrophes of military medicine in this century have been due neither to tupidity nor to callousness but to too much rigidity f direction or equipment In Korea evacuation rom the line has been largely by ambulance as far s railhead , but, owing to the poor state of the oads, ambulance trains have been preferred for transport to the rear Helicopters have been employed for he transport of the seriously wounded from forward reas, and casualties have mostly been removed to Japan or the U S.A. by air, though some have travelled by sea [1]

Among all the changes in surgical practice in the field between 1939 and 1945, " forward " surgery by experts, followed by rapid evacuation, was probably the most revolutionary and the most rewarding It is a principle rather than a drill, and, as applied in Korea, appears to have been gratifyingly successful Figures so far suggest that the mortality among wounded is about $2^1/_2\%$ as against an over-all average of 4% in the last war Those who remember hoarding a few thousand milligrammes of penicillin in 1943 will smile to hear of the huge supplies of antibiotic drugs available First impressions suggest that 'Terramycin,' because of its "polyvalency," is especially useful in forward areas A novel hazard for the American and British forces has been the cold special clothing has been required, and an interesting experiment' is the training of N C O s of all arms to decide the clothing needs of the moment and to recognise the exhausted soldier who must be sent to the " warming tent " for recovery But of casualties due directly to cold less than 10% have had to be evacuated from Korea Keeping the wounded man warm is a problem not yet solved Plastic bags in which the patient and his blankets can be inserted have proved satisfactory, but those in use so far have been too heavy and bulky for forward areas

We have heard those who would excuse war for the advances in medical knowledge which result We cannot agree , but it would be foolish to deny that these advances occur, and it is unlikely that the war in progress will be without benefit in this way Chloroquine is now the standard drug in the U S army for the suppression of malaria and has been found satisfactory The disciplinary advantage of weekly rather than daily dosage is thought to outweigh the risk of relapse , and the treatment of the latter with primaquine, a new product, is under trial Methadone *vice* morphine has also won approval, and in its iso lævo isomer produces less nausea and is better tolerated by those who must make long journeys by air Experience is accumulating in the use of dextran and other plasma substitutes Intramedullary pins have been used largely in the treatment of fractures of long bones, and we shall be glad to hear more of a casein resin splint, lighter and stronger than plaster-of-paris For burns, and with an eye to damage from atomic explosions, a huge water- and bacteria-proof dressing 19 in by 36 in has been used , though effective, it is difficult to hold in place and for this purpose a simple technique for rendering a cotton bandage elastic has been devised All these in their own way seem to promise improvements in surgical technique, and we shall look forward to critical reports in the future In preventive medicine two novelties under trial deserve description Iodine and not chlorine seems to be the active agent in a new water sterilising tablet which is at any rate moderately lethal to cysts of *Entamœba histolytica* It has its failings , it turns starchy foods blue and the water brown, but the taste is no worse than that of chlorinated water Of far more general interest is actidione, a by-product in the making of streptomycin, which is reported to be an effective repellant of rats Such pleasure as this will bring the quartermaster will be negligible compared to that of the farmers and millers of the whole world If the claims for actidione are well founded and it can be produced at a reasonable cost (which it cannot be at the moment) it is a discovery of the first magnitude

It is a common and not unreasonable complaint that war and the threat of war drive the springs of scientific inquiry underground We are therefore unusually grateful to the Office of the Surgeon General in Washington for giving so much news of the doings of his department in Korea It is stimulating to us and can be of no comfort to the enemy

ADDENDUM TO THE B P

THERE is just enough of the element of surprise in a new pharmacopœia or an addendum to an existing one to arouse in the pharmacologist or pharmacist some of the emotions that other people get from a lottery draw or the Chancellor's Budget speech The *Addendum to the British Pharmacopœia, 1948*, which was published on April 19 and will become official on Sept 1, includes over 40 additions and over 50 amendments to existing monographs The additions sometimes reflect a prompt recognition of the value of some recently introduced drug, like chloramphenicol, and sometimes a more gradual establishment of a drug's status—for example, the anti histamine drugs mepyramine maleate and promethazine hydrochloride ('Anthisan' and 'Phenergan') are now official Other newcomers are D D T , under its previously approved name of dicophane , isoprenaline sulphate (isopropyl noradrenaline), and methacholine chloride (acetyl β methylcholine hydrochloride, or 'Mecholyl') Among the antibiotics, besides chloramphenicol, the addendum includes *streptomycin* (three salts and their injection preparations), and crystalline penicillin G, officially known as benzylpenicillin. Procaine benzylpenicillin is also listed and will be dis-on coordination and settle matters in dispute They also disapprove—with reason, we think—the novel proposal to establish statutory registers for purposes of the National Health Service only, which may mean "that more than one standard of basic qualification may be recognised within a single profession"

In bringing his flotilla of committees into port, Commodore Cope would no doubt have liked to see the crews unitedly pulling in the same direction Nevertheless, the lack of unanimity is proof of vitality and it usefully displays some rapidly developing stresses in the structure of medicine The minority report we have quoted makes out a good theoretical case, and it is certainly hard to see why almoners and physiotherapists should be offered a lesser degree of professional independence than, for example, nurses On the other hand most of us are convinced that the fragmentation of medicine has already gone too far, and that the time has come, in the interest of patients, to reassert the true doctor's predominance over technicians of whatever kind Which takes us back to Dr Rabson's disturbing letter

Surgery of Mitral Disease

Advances in surgery, like the final chapters of good detective novels, never seem to develop in a way that can be foreseen Mitral stenosis has always offered a challenge to the surgeon, because enlargement of the stenosed opening should relieve most of the symptoms Numerically this is an important problem, in the U S A Paul White[1] has estimated that 0 5–1% of the population have valvular disease as a sequel to rheumatic fever, and in Britain the figure can hardly be less

An operation for the relief of mitral stenosis was proposed almost fifty years ago by Sir Lauder Brunton,[2] yet it is only in the last couple of years that such an operation has been performed on any scale This latter day progress is due partly to advances in related fields, notably the introduction of new anæsthetic drugs, muscle relaxants, and controlled respiration, the discovery of potent anti biotics, and better understanding of fluid and electrolyte requirements after operation The foundation of the present improved position in cardiac surgery was laid in the middle '20s by Cutler and Beck[3] in Boston, Souttar[4] in this country, and others, who made a direct surgical attack on the stenosed mitral valve The mortality rate proved too high, and during the next ten years cardiac surgery was largely restricted to removal of foreign bodies It was during this decade, however, that investigations into respiration progressed so well that thoracic surgery was robbed of many of its dangers These advances will always be associated particularly with three names Tudor Edwards of London, Edward Churchill of Boston, and Crafoord of Stockholm Subsequently great strides were made in the surgery of congenital defects of the heart and great vessels Gross tied the patent ductus arteriosus, Crafoord resected coarctation of the aorta, and Blalock anastomosed the subclavian and pulmonary arteries to relieve the cyanosis of Fallot's tetralogy Pulmonary stenosis being mainly responsible for the cyanosis in this condition, Brock made a direct surgical attack with valvulotomy, and the success of this procedure led him to try a similar operation for mitral stenosis His latest report to the Royal Society of Medicine is summarised on an earlier page of this issue

Brock has performed valvulotomy for mitral stenosis in 48 cases, there have been 8 deaths, but none in the last 24 cases In Philadelphia Bailey and his associates,[5] who have proceeded along similar lines, have operated on 50 patients with 8 deaths, they call the operation commissurotomy—a term suggested by Durant of Philadelphia From Paris[6] and Montreal[7] come similar accounts of successful operative relief, and in this country and elsewhere many surgeons have been perfecting their operative technique As a result of this rapid progress cardiologists are likely to find themselves called on to decide which cases are most suitable for operation, and Dr Maurice Campbell is to be congratulated on his most successful collaboration with Mr Brock in this field It has already been shown that younger patients survive valvulotomy best and derive most benefit from it This is probably because they have escaped the changes which accompany long standing back pressure in the pulmonary circulation, one of Bailey's patients who died three days after a commissurotomy[8] was found to have pulmonary changes which accounted for death Patients with Lutembacher's syndrome are known to withstand mitral stenosis well because their atrioseptal defect allows a left to right shunt Sweet devised an operation utilising the azygos vein to relieve the pulmonary pressure, and there may still be a place for this type of manœuvre in patients with mitral stenosis of long standing in whom valvulotomy alone is unlikely to be of much help Blalock's operation for making an atrial septal defect may be of use for the same reason

Meanwhile we need some modern Oliver Wendell Holmes to devise a word for the new operation, which neither "valvulotomy" nor "commissurotomy" quite describes

Medical Services in Korea

The opening of the campaign in Korea did not find the medical services of the army of the United States entirely unprepared Equipment for field medical units was in store, assembled and ready for issue, while the garrison in Japan provided personnel enough for three mobile surgical hospitals and an evacuation hospital That these, though hard worked, were just sufficient to handle the casualties of the four U S divisions confined within the Pusan perimeter was due to numerous base hospitals having been already established in Japan, 140 miles away and 45 minutes by air As the number of combatants increased, so did the number of medical units, and, though these have accepted responsibility for the familial allergy, emphysema, nasal allergy with lyposis, and eosinophilia It is thought that aspirin not an allergen per se, but that it combines with dy proteins (perhaps the circulating globulins) to m specific allergens or haptens which evoke the ictions The dangers of aspirin sensitivity should vays be considered when prescribing aspirin for thmatics and allergic subjects

A PSYCHODRAMATIC EVENING

GROUP psychotherapy has received increased attention nce the late war, with its large number of psychiatric isualties among Servicemen and civilians, forced sychiatrists to look around for methods of treating ieir patients en masse rather than individually The pproaches have been many, depending largely on the emperament and experience of the proponent they inge from the inspirational, semi revivalistic techniques f L C Marsh at Worcester State Hospital, A A Low ith his "Recovery, Inc" in Illinois, and Alcoholics nonymous, through the educational methods of E W. azell, to the analytical approach of S H Foulkes and Bion—to instance but a few of the pioneers on both ides of the Atlantic

The continued interest of psychiatrists and their co vorkers in this matter was shown in London on April 9, vhen a large audience witnessed a demonstration of sychodrama by Dr J L Moreno, presented under the uspices of the Institute of Social Psychotherapy Dr Moreno was one of the first psychiatrists to apply group methods, beginning work with neurotic children n Vienna in 1911, the children were encouraged to ict out their fantasies, and in this way psychodrama evolved Later the method was applied to adult patients and introduced by Dr Moreno to the U S A., the first psychodrama theatre connected with a hospital was built in 1936 at Beacon Hill, New York, where Dr Moreno's sanatorium and Institute of Sociatry is the headquarters and training school of his movement throughout the U S.A At the meeting Dr Moreno began by recalling that drama had evolved from religious group activities, first one and then more than one participant being pushed forward to enact and voice the group's emotions The hall in which he was speaking conditioned, he said, the response of his audience, for he was on a platform, cut off from his hearers by height and distance His psychodrama theatre or, as he preferred to term it, "spontaneity theatre" had a low, semicircular stage projecting into the auditorium with shallow steps leading down from stage to audience In the front row sat his specially trained assistants who as "auxiliary egos" could be called on by a patient to enact the rôle of the patient himself or of anyone in his emotional story—father, mother in law, wife, child, boss, and so forth Behind the auditorium was a gallery, reserved for "superegos," and useful on one occasion when he had a patient with a remarkable resemblance to Adolf Hitler, moustache and all, who was provided with auxiliary egos to represent the Führer's entourage and was allowed to address the crowd from above This patient, via a mildly homo sexual friendship with his pseudo Goering, eventually made a social recovery

By now Dr Moreno had got into his stride, and was pacing up and down the stage and making sorties into the audience, every muscle in his face and body used with the fluent abandon of the born actor, so that a press photographer and his flashlamp assistant, pussy footing down the aisles were hard put to it to capture his split second gestures They caught one dramatic moment, when Dr Moreno was making believe to strangle the chairman to illustrate what he called mirror acting This was further enacted by Mrs Moreno and a volunteer from the audience In mirror acting the depressed or catatonic patient may be drawn into participation by trained assistants who have studied his case enacting before his eyes the way that he behaves A typical marital problem was acted by a London psychiatrist and Mrs Moreno, starting from the breakfast table squabble over wifely extravagance and hubby's more than professional interest in his secretary, and continuing to the interview of the aggrieved lady with her solicitor—a rôle in which the psychiatrist showed a ready wit and nice opportunism by advising her to consult a psychiatrist Lastly, the importance of the "double" was demonstrated, this being Dr Moreno's term for the imaginary other self with whom each of us carries on a lifelong, not always silent, colloquy This was charmingly and gallantly done by a young newly married Norwegian girl from the audience, ruminating aloud in our foreign tongue on how she expected to feel seeing her parents for the first time since her marriage, with Mrs Moreno skilfully voicing the dubieties and homely aphorisms of her alter ego, and, in the background, Dr Moreno, resourceful as Prospero and lively as Ariel, perpetually darting, prompting, questioning

TUBERCULOSIS IN SCOTLAND

IN Scotland mortality from tuberculosis continued to rise in the years after the end of the late war, but in 1950, as we noted last week,[1] the rate fell to a level 15 per 100,000 below the average for the previous five years In its latest report[2] the Royal Victoria Hospital Tuberculosis Trust observes that definite improvement has taken place "during a period when every public utterance has proclaimed not only the lack of adequate measures for controlling the disease, but the supposed deterioration of facilities which had existed previously" The report draws attention to the epidemic nature of tuberculosis, and rightly attributes the deterioration after 1939 to changes, both mental and physical, in the human soil. It ascribes the failure of the mortality rate to improve in the post war period up to 1949 to the delayed effects of increased infection and morbidity in the war years Infection must also have increased in England and in other countries where mortality, after a war time rise, fell in the immediate post war period, and it seems possible that the main cause of the post war situation in Scotland may have been the less satisfactory pre war conditions, perhaps exaggerated by war time influences In the words of the report "Better developed services in England, particularly better facilities for isolation and treatment, probably influenced the epidemic in that country at an earlier stage" The report attributes the recent fall in mortality to the recession of the epidemic wave initiated by the war, but the fall has coincided with the general introduction of chemotherapy, which may have played an even more important part than the natural recession

It is pointed out that both developmental changes associated with puberty, and recently acquired infection, are important causes of the high mortality among adolescents, especially females, and the high mortality in older men is reasonably attributed to recrudescence of old latent foci, but no mention is made of the "generation" method of analysing mortality rates, to which attention has been drawn in our correspondence columns[3] Such an analysis adequately explains the present high rates of mortality in older males without invoking the "stresses and strains of life and of adverse social and economic factors" These factors, no doubt, are important, as the report says, in determining the general pensed when procaine penicillin is prescribed Other monographs deal with ethinyloestradiol, cetrimide ('Cetavlon'), propylthiouracil, oxyphenarsine, and quinalbarbitone ('Seconal') There are 8 new monographs on preparations of blood, and presumably because of the inclusion of whole blood an appendix has been added on ABO and Rh group testing

ANGOR ANIMI

> WHAT a strange force it is that can stir, and with such intensity, a consciousness of the imminence of an event of which there can never have been any actual experience, and yet is so frequently inoperative when death is at hand'

So wrote Dr John A Ryle, assistant physician to Guy's Hospital, in 1928[1] Fourteen years later, and until his death in 1949, Professor Ryle had many opportunities to study in his own person the symptom that had interested him so much Characteristically he noted down his experience, and left the paper to be published in *Guy's Hospital Reports*, as a postscript to his earlier speculations Both papers, and a further postscript written by his son, Dr J C Ryle, have been printed together[2] In both papers, Ryle's concern was to suggest a possible physiological interpretation of the fear of impending death, or more properly the sense of dying, often described as a component of anginal attacks In the earlier paper he noted that those who have studied it closely agree that the sensation is a physical one, Clifford Allbutt referred to it as an "organic sensation" It occurs not only in angina pectoris but also, independently of any demonstrable organic change, in vasovagal attacks, and whereas in angina the sensation is as transient as the pain, in vasovagal attacks it may last much longer, and appear much oftener Ryle had never seen it, in its major form, as a symptom of psychological disease, and he found that though it may be possible to allay the patient's anxiety by assuring him that his feelings are liars, yet the symptom itself cannot be removed by reassurance or by any other psychotherapeutic measure

The associated symptoms, Ryle suggested, give a clue to the site of the physical disturbance In both anginal and vasovagal attacks the patient is unwilling to make the smallest movement, and even his breathing is restricted John Hunter, in his initial attack of angina, found himself not to be breathing at all, and started again by an act of will During vasovagal attacks—of which Ryle reported 13 cases—there was often, he found, coldness, pallor, palpitation, and quickened or sometimes a very slow pulse, the patients might have a sense of unreality and lose consciousness for a time, and many of them complained of pain or discomfort between the precordial area and the left clavicle, with a tugging pain up the left side of the neck Angor animi was present in 11 of these 13 patients, as against only 6 out of his 43 patients with angina pectoris However, he had encountered the symptom in one case each of angina abdominis and angina cruris, in a case of spasmodic Raynaud's disease, and in association with labyrinthine vertigo, and had seen notes of a case associated with a tumour involving the medulla oblongata The common factor in all these conditions, he thought, must be a powerful medullary stimulus of some kind, with physical effects manifested in disturbances of the cardiac, respiratory, and vasomotor functions The sense of dying itself he described as "the aura of a nervous storm having its vortex in those medullary centres upon which the act of living depends" In vasovagal attacks, as in epilepsy and migraine, the origin of the storm is unknown, but in angina and Raynaud's disease it might well be due to impulses arriving from the aorta, or the coronary or peripheral arteries, in moments of arterial stress or spasm, and passing via the medullary nuclei Angor animi, in fact, might be the sensory part of a strong immobilisation reflex intended to protect life and give the distressed heart the best chance of weathering the storm

Ryle's later experience gave him no reason to revise this theory, but he was able to describe in careful detail the sensation of dying and the symptoms associated with it It was most liable to befall him when he had dropped into a pleasant sleep after doing rather too much and increasing his hyperpiesia He was roused abruptly, on these occasions, by a surging sensation behind the sternum, spreading into the head and neck and down the arms, and associated with the indescribable conviction that he was dying There was no feeling of faintness or failure of consciousness, and no pronounced changes in pulse rate or colour He thought the full relaxation accompanying sleep might have resulted in a sudden fall in pressure, which in turn had precipitated the attack, and he found that a few deep breaths cut short the sense of dying Like John Hunter he had to take them deliberately, for his breathing sometimes seemed to be arrested by the attack The heart he suggested, at a time of muscular anoxia, announced its distress by pain and by a secondary arrest of bodily movements, and might induce a reflex respiratory inhibition as well The biological purpose of the whole episode would thus be a warning or protective one Other painful crises—such as renal or biliary colic—"lacking the associated hazard of angina," are not associated with a sense of impending death Nor had he ever found the symptom in hyperpiesia unaccompanied by coronary disease

Among other unanswered questions about this curious sensation, he asked "Will it ever be possible for a keen observer to signify in his last seconds of life whether or not the sense of dying was present?" His son partly answers for him in a final postscript "The symptom of angor animi remained with him up till his third coronary thrombosis about two weeks before his death, thereafter anginal pain was replaced by failure and he did not mention the symptom again During this time he believed with good reason on three occasions that death was imminent, but though perfectly rational did not make any reference to angor animi"

ASPIRIN SENSITIVITY

IT is perhaps not generally realised that aspirin can cause allergic manifestations in susceptible patients Physicians are so used to regarding this as a perfectly safe drug that when prescribing it they rarely pause to consider the possibility of drug allergy Even if they do they are unlikely to remember all the proprietary drug mixtures containing aspirin Bearing in mind the wide use of the drug, sensitivity is rare, but a patient's statement that he cannot tolerate it, and that it may induce asthma or urticaria, should always be heeded Other manifestations of aspirin sensitivity are angioneurotic oedema, allergic rhinitis, and cardiovascular collapse

Fatalities have been reported in bad asthmatics, and many workers have remarked that aspirin sensitivity tends to arise in the most severe and intractable cases of asthma with a poor prognosis, and that skin tests with the drug are often not only negative but highly dangerous In a series of 830 asthmatics Walton and Bottomley[1] observed 22 cases of aspirin sensitivity—an incidence of approximately 2 5%—and half of them had severe asthma Others have described an incidence of 2–10% among all asthmatics, with females more often affected than males In these cases there is a high incidence of familial allergy, emphysema, nasal allergy with polyposis, and eosinophilia. It is thought that aspirin is not an allergen per se, but that it combines with body proteins (perhaps the circulating globulins) to form specific allergens or haptens which evoke the reactions The dangers of aspirin sensitivity should always be considered when prescribing aspirin for asthmatics and allergic subjects

A PSYCHODRAMATIC EVENING

Group psychotherapy has received increased attention since the late war, with its large number of psychiatric casualties among Servicemen and civilians, forced psychiatrists to look around for methods of treating their patients en masse rather than individually The approaches have been many, depending largely on the temperament and experience of the proponent they range from the inspirational, semi revivalistic techniques of L C Marsh at Worcester State Hospital, A A. Low with his "Recovery, Inc" in Illinois, and Alcoholics Anonymous, through the educational methods of E W Lazell, to the analytical approach of S H Foulkes and J Bion—to instance but a few of the pioneers on both sides of the Atlantic

The continued interest of psychiatrists and their co-workers in this matter was shown in London on April 9, when a large audience witnessed a demonstration of psychodrama by Dr J L Moreno, presented under the auspices of the Institute of Social Psychotherapy Dr Moreno was one of the first psychiatrists to apply group methods, beginning work with neurotic children in Vienna in 1911, the children were encouraged to act out their fantasies, and in this way psychodrama evolved Later the method was applied to adult patients and introduced by Dr Moreno to the U S.A., the first psychodrama theatre connected with a hospital was built in 1936 at Beacon Hill, New York, where Dr Moreno's sanatorium and Institute of Sociatry is the headquarters and training school of his movement throughout the U S.A At the meeting Dr Moreno began by recalling that drama had evolved from religious group activities, first one and then more than one participant being pushed forward to enact and voice the group's emotions The hall in which he was speaking conditioned, he said the response of his audience for he was on a platform, cut off from his hearers by height and distance His psychodrama theatre or, as he preferred to term it, "spontaneity theatre' had a low, semicircular stage projecting into the auditorium with shallow steps leading down from stage to audience In the front row sat his specially trained assistants who as "auxiliary egos" could be called on by a patient to enact the rôle of the patient himself or of anyone in his emotional story—father, mother in law, wife child boss, and so forth. Behind the auditorium was a gallery, reserved for 'superegos," and useful on one occasion when he had a patient with a remarkable resemblance to Adolf Hitler, moustache and all, who was provided with auxiliary egos to represent the Führer's entourage and was allowed to address the crowd from above This patient, via a mildly homosexual friendship with his pseudo Goering, eventually made a social recovery

By now Dr Moreno had got into his stride, and was pacing up and down the stage and making sorties into the audience, every muscle in his face and body used with the fluent abandon of the born actor, so that a press photographer and his flashlamp assistant pussyfooting down the aisles were hard put to it to capture his split second gestures They caught one dramatic moment, when Dr Moreno was making believe to strangle the chairman to illustrate what he called mirror acting This was further enacted by Mrs Moreno and a volunteer from the audience In mirror acting the depressed or catatonic patient may be drawn into participation by trained assistants who have studied his case enacting before his eyes the way that he behaves A typical marital problem was acted by a London psychiatrist and Mrs. Moreno, starting from the breakfast table squabble over wifely extravagance and hubby's more-than-professional interest in his secretary, and continuing to the interview of the aggrieved lady with her solicitor—a role in which the psychiatrist showed a ready wit and nice opportunism by advising her to consult a psychiatrist. Lastly, the importance of the "double" was demonstrated, this being Dr Moreno's term for the imaginary other self with whom each of us carries on a lifelong, not always silent, colloquy This was charmingly and gallantly done by a young newly married Norwegian girl from the audience, ruminating aloud in our foreign tongue on how she expected to feel seeing her parents for the first time since her marriage, with Mrs. Moreno skilfully voicing the dubieties and homely aphorisms of her alter ego, and, in the background, Dr Moreno, resourceful as Prospero and lively as Ariel, perpetually darting, prompting, questioning

TUBERCULOSIS IN SCOTLAND

In Scotland mortality from tuberculosis continued to rise in the years after the end of the late war, but in 1950, as we noted last week,[1] the rate fell to a level 15 per 100,000 below the average for the previous five years. In its latest report[2] the Royal Victoria Hospital Tuberculosis Trust observes that definite improvement has taken place "during a period when every public utterance has proclaimed not only the lack of adequate measures for controlling the disease, but the supposed deterioration of facilities which had existed previously" The report draws attention to the epidemic nature of tuberculosis, and rightly attributes the deterioration after 1939 to changes, both mental and physical, in the human soil. It ascribes the failure of the mortality rate to improve in the post war period up to 1949 to the delayed effects of increased infection and morbidity in the war years Infection must also have increased in England and in other countries where mortality, after a war-time rise, fell in the immediate post war period, and it seems possible that the main cause of the post-war situation in Scotland may have been the less satisfactory pre-war conditions, perhaps exaggerated by war-time influences In the words of the report 'Better developed services in England, particularly better facilities for isolation and treatment, probably influenced the epidemic in that country at an earlier stage" The report attributes the recent fall in mortality to the recession of the epidemic wave initiated by the war, but the fall has coincided with the general introduction of chemotherapy, which may have played an even more important part than the natural recession

It is pointed out that both developmental changes associated with puberty, and recently acquired infection, are important causes of the high mortality among adolescents, especially females, and the high mortality in older men is reasonably attributed to recrudescence of old latent foci, but no mention is made of the "generation" method of analysing mortality rates, to which attention has been drawn in our correspondence columns.[3] Such an analysis adequately explains the present high rates of mortality in older males without invoking the "stresses and strains of life and of adverse social and economic factors' These factors, no doubt, are important, as the report says, in determining the general level of mortality, but they hardly explain the progressive change in the age distribution of mortality Whilst accepting B C G as of proven value in preventing morbidity and mortality among young adults who have not previously been infected, the report very properly insists that there must be no slackening of efforts to isolate and treat those who have the disease and are infectious Such a reminder is welcome, especially as the Scandinavian countries, from which comes much of the evidence for the value of B C G, have also very efficient services for the identification, isolation, and treatment of sources of infection

NATURAL CAUSES OF SUDDEN DEATH

To the pathologist the cause of sudden death is usually clear, but occasionally it can only be conjectured This is borne out in a series of reports, by Helpern and Rabson,[1–5] on 2030 such deaths from natural causes in the borough of Manhattan during the years 1937–43

The greatest incidence was in the two 5 year age groups between 45 and 54, and diseases of the heart and aorta accounted for 54% of the total[2] Coronary artery disease alone was the cause in 30 4% but a recent thrombus was found in only just over a quarter of these of all the deaths from coronary artery disease only 6% were in women, none of whom was coloured In fact slightly more than 90% in this group were white males and only 3 7% negroes, although the latter formed 14 5% of the male population, and this discrepancy is still great even assuming that all visitors to Manhattan are white males, in which event the negro male population would be 9 4% (By contrast, among negroes deaths from ostial obstruction due to syphilitic aortitis were relatively common, totalling 39% of the deaths from this cause) The incidence of coronary artery disease reached its peak in the 5 year age group between 50 and 54 and then gradually fell Death took place in the street, while at work, or in a public place in 47% of instances Of those who died suddenly at home, half were in bed at the time Hotel deaths usually took place in bed, "though not always following a night of rest and relaxation" In 56% of the cases examined the heart weight exceeded 400 grammes, while more than half of the enlarged hearts exceeded 500 grammes

Diseases of the respiratory tract accounted for 23 2%, and pulmonary tuberculosis for 3 4% of the deaths, tuberculosis provided an appreciable number of the unexpected deaths in middle and later life Diseases of the nervous system were responsible for 18 2% of the deaths, and disorders of the digestive system for 6 5% the urinary tract furnished 2 0%, and the genital system only 1 3% Ruptured tubal pregnancy, however, accounted for 16% of the total female deaths in the age group 20–24, 19% at 25–29, 17 5% at 30–34, 8% at 35–39, and under 6% at 40–44

The third paper[3] deals with subarachnoid hæmorrhage, which was the cause in 4 6% of all the deaths and in 25 7% of those due to diseases of the nervous system, this cause was in fact little less common than cerebral hæmorrhage (30 4%) Fatalities from this disease were most common in late youth and, more especially, middle age In two thirds of the cases an aneurysm was found, the most usual sites being the middle cerebral and anterior communicating arteries Occasionally an aneurysm may produce a misleading picture, as when rupture takes place high up in the fissure of Sylvius and forms a localised hæmatoma between the island of Reil and the overlying cortex this may readily be confused with intracerebral hæmorrhage Sometimes subarachnoid hæmorrhage may rupture into the subdural space and so resemble subdural bleeding from trauma. Of the 95 cases of subarachnoid hæmorrhage, 43 died at home, 10 being found in bed, in 14 cases the subject was walking when the symptoms began Alcohol estimations were sometimes carried out on post mortem material, and positive values were found to exceed the negatives by three to two Possibly the earliest symptoms may have led to the imbibing of alcohol, but Helpern and Rabson believe that alcoholic intoxication may be a precipitating factor, for the resulting active hyperæmia may throw an added burden on the cerebral circulation Alcohol also increases the chances of altercation, and thus the liability to cerebral trauma

As to sudden death in young children,[4] this was rare beyond the age of 3 years, and most of the fatalities were in males This supports the old observation that boy babies are more liable to die in infancy than are girls—a feature which tends to counterbalance the initial preponderance of male over female births The proportion of sudden deaths in negroes in this age-group was far beyond their proportion in the population, this Rabson attributes to their lower economic status Respiratory diseases accounted for almost 80% of the deaths, microscopic studies usually substantiated the diagnosis, but sometimes another cause of death was brought to light, and very occasionally no adequate reason could be found Bronchitis and bronchopneumonia were two and a half times as common in male babies as in females, whereas in older children diseases of the digestive system provided twice as many deaths in girls as in boys, and diseases of the heart and aorta four times as many The majority of the problem cases were of infants between the ages of 4 and 8 months, often no adequate cause of death could be found Asphyxia was not recorded, Rabson believes this to be a rare cause of death in infants found dead in their cribs, for the aspiration of vomitus may complete the lethal circle of an obscure primary condition and mislead the inexperienced (In this connection we remarked last year[6] that "the assumption that infants are easily suffocated is untenable, for all except very young and feeble infants react vigorously to a feeling of impending suffocation, and certainly do not allow themselves to be asphyxiated by turning their face to a pillow") In difficult cases one must avoid invoking status lymphaticus, it is far better to recommend certification of death as "by act of God" In the case of a 5 month old Chinese girl, however, the thymus weighed 77 grammes, and the adrenals, by contrast, only 2 82 grammes She was found dead in her crib lying on her side, just as she had been placed Death was attributed to the enlargement of the thymus, for there was distinct antero posterior compression and narrowing of the lumen of the trachea Why death took place when it did was not clear

An unusual cause of death, judging by experience in the United Kingdom, was malaria in drug addicts The pooling of needles, syringes, and drugs by these unfortunates returning from war is regarded as the reason for the spread of malaria in Manhattan, and in the age-group 20–24 it accounted for 8 3% of the sudden deaths. Pitting scars on the arms and legs usually drew attention to the possibility of this source of infection

POLIOMYELITIS

Some fin-de-saison Reflections

DAVID LE VAY
M S Lond., F.R C S
ORTHOPÆDIC SURGEON, BROOK GENERAL HOSPITAL, LONDON

> "There is no question that a lot of treatment (for poliomyelitis) is still being given undue credit which rightly belongs to the Lord, and not to any orthopædic surgeon or physiotherapist I would not go so far, however, as to say that any sort of treatment is useless (Steindler 1947)

IT seems likely that major epidemics of infantile paralysis will recur annually in this country in future, and that we shall have to face the situation—which has already existed in North America for a long time—that each succeeding year brings many thousands of fresh cases, a considerable proportion of which are paralytic

In the past, when cases were fewer, it was usual for patients to be retained in fever hospitals until the end of an arbitrary quarantine period, after which, if there was any severe residual paralysis, they were transferred to long stay orthopædic units In view of the trend of the disease these arrangements may now be open to criticism In some cases there may be little or no useful physiotherapy and orthopædic supervision during the all important early quarantine period, when overstretching and contracture begin, the patient's later stay under definitive orthopædic care may be remote from home and family and the main stream of town life, and, as one consequence, practical experience in the management of infantile paralysis is lacking in the ordinary urban hospitals which may now, as the burden increases, have to take their share of this work

Such criticism is admittedly by no means everywhere applicable The system is a natural one and has so far worked fairly well As Clarke (1950) says of orthopædic work in general "a city hospital is unsuited for the treatment of chronic illness The rôle of these hospitals is to act as after care clinics for the collection, treatment, and supervision of outpatients It is important therefore that close working liaison should be established between town and country hospitals" But this is a counsel of perfection We are already hard pressed for hospital beds and services, partly because of the demands made on urban hospitals for the care of the chronic sick and the aged If changes are needed in the immediate future, so far as poliomyelitis is concerned, one reason will be that too few beds are available, *when wanted*, in the old-established peripheral orthopædic hospitals It is vital to ensure that young and valuable members of the community are not discharged prematurely to their homes for lack of those inpatient orthopædic and rehabilitation facilities which are still by no means readily found even for early cases of skeletal tuberculosis

I view this matter in the light of the experience of the management of nearly 200 cases of poliomyelitis of which 140 were paralytic, at the Brook General Hospital during the last three years Until July 5, 1948, this was purely a fever hospital, but since then it has become a general medical and surgical hospital, containing a modern fever unit of 130 beds It was felt that the tradition of early admission to fever hospital and subsequent transfer to a long stay centre should be abandoned, partly because it became increasingly difficult to obtain places in those institutions when they were wanted, but more because the continuity of treatment was broken by such transfer Only 25 of our patients were so transferred, largely because of overwhelming pressure on beds at the height of the epidemic season, or because of the need of education in long term cases in children, or because special facilities, such as large pool therapy, were thought desirable

We sometimes had occasion to regret having made a transfer, and even to readmit patients who had been prematurely discharged from other centres It has been our experience that, except when pressure on beds makes it necessary to use isolation cubicles for their primary purpose only, the need for transfer is negligible when the fever unit works in close liaison with general beds cared for by the same orthopædic and physiotherapy staff, and we now retain our patients until their final discharge home The advantages to them in remaining under the same supervision throughout are obvious

The problem is cumulative Current work includes the victims of the epidemics of the past few years as well as the fresh cases As with another major medicosocial problem, that of pulmonary tuberculosis, the solution—or at any rate a provisional solution—lies in bringing these patients back into the atmosphere of the general hospital Here the fever hospitals, now largely overbedded for their original responsibilities, thanks to the improvement in the public health, may play an important part I agree with James (1951) that these hospitals, largely deprived of their clinical bread and butter by the decline in diphtheria and scarlet fever, should now be used as general hospitals James thinks in terms of a cubicled fever unit, in the charge of a physician experienced in fevers, embedded in a general hospital with provision for pathology, radiology, and surgery He finds that this arrangement works well, that the catholicity of the experience retains medical staff of good calibre and student nurses who might otherwise drift away, and that the greatest benefit is to the patient This is the same as the set up at Brook Hospital, it has worked very well, and is ideal for the city victims of infantile paralysis

Treatment

The routine after admission is for all poliomyelitis patients to be nursed flat on fracture boards Children and light young adults have no pillow or mattress and only four folded layers of blanket over the boards, most adults have a hair mattress and one small pillow A pad behind the knees prevents hyperextension, and bed cradles and sand bags keep the feet from dropping When the deltoid muscles are obviously affected, the arms are fixed with cuff and bandage to the upper bed rail to hold the shoulders abducted

Preliminary *muscle charting* is done as soon as possible, but may be postponed for a few days if need be It is an ordeal in the acute case, and we are reluctant to require any activity which may worsen the paralysis during the early days, even lumbar puncture is not done when the diagnosis is obvious It is realised that this first chart may not be a fair guide, since coöperation is not good when pain and spasm are present, the real starting point may not be obtained until several charts have been made at intervals of a few days and the patient has made a good effort to coöperate After this, charting is done every three or four weeks There is no need here to emphasise the cardinal importance of obtaining some sort of chart, however sketchy, if any idea of progress is to be formed, it is the compass which enables one to guide the patient from stage to stage of his journey With tiny children chart making may require infinite patience perhaps limited to quietly sitting and watching their activities

SPLINTS

In general we think it better to use too few splints than too many, (1) because efficient daily physiotherapy will prevent contractures, and (2) because oversplintage tends to deprive small children of the sense of the use of their limbs When splints are used they are removed for long periods by day so that the patient can do what he likes with his muscles

The main indications for light plaster splints are to maintain abduction for deltoid paralysis in infants who wriggle so much that mere tying of the arm to the bed does not suffice, and to hold the foot at a right angle Elsewhere, elastic splints are used where necessary—e g, the thumb can be comfortably supported in opposition with 'Elastoplast,' when the opponens muscle is paralysed, allowing the first web space to be stretched regularly

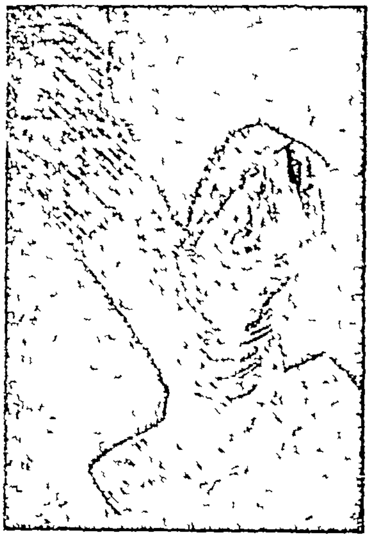

Fig 1—Wooden cross-bar incorporated in foot splint to prevent external rotation of lower leg

Little is to be gained by the use of long arm or leg splints If one wants to hold an elbow at right angles, this can be done efficiently with a collar and cuff, and in the legs it is enough to see that the popliteal pad prevents full extension We have been impressed with the importance of seeing that external rotation of the leg does not produce a chronic strain of the internal lateral ligament of the knee, as may happen insidiously in a flail lower limb when the foot and leg fall outwards As Yachnin (1947) points out, the axis of rotation at the knee is inside the midline of the joint, and the main mass of the limb outside, the joint is more lax when its supporting muscles are paralysed, and when the lower limb falls into external rotation from the hip downwards it is the portion below the knee which rotates abnormally This rotation strains the internal ligament and *may become permanent, with severe pain and* stiffness which may persist for a year or two Such a deformity is easily prevented by incorporating a wooden cross bar in the foot splint (fig 1) When a limb is completely flail, and careful repeated observation shows not the slightest sign of recovery, the splint is discarded and reliance placed merely on passive movements to prevent stiffness and to preserve the proprioception which will be needed later for walking in a calliper But such writing off must be done with caution The deltoid muscles in particular show amazing powers of recovery, which may never take place if the small spark of power is allowed to be extinguished by overfatigue

PHYSIOTHERAPY

This is begun at once, with the following provisos (1) in the very ill patient and in the earliest days it is probably harmful to interfere, and (2) it must be remembered that some cases will continue to deteriorate during the first few days after admission Patients with only mild scattered paresis on the day of admission may develop flail limbs in a few days and be in the respirator by the end of the week Lenhard (1950) says

> "Treatment for the poliomyelitis patient is commonly translated into an urge to do something The more that is done for the patient, the better the therapist feels The greatest need in the early stage is rest for the patient and the muscles involved, they do not require, nor should they have, much physical therapy"

This is true enough, but it is also true that there is an essential minimum of treatment which these patients must have We usually begin treatment before the end of the first week, and at once in those cases where the patient has been ill at home for some days before admission and is obviously ready to recover Only so much attention is given as is needed to keep the joints mobile, and all joints are given a full passive range once daily If every plane of movement is not kept in mind, unexpected contractures may develop—e g, abduction contracture of the hip, with adductor paralysis

TREATMENT OF PAIN AND SPASM

The obstacles to daily movement are pain and spasm, usually, though not always, found in association

What is the source of this pain? Though it is difficult to answer this question for every patient, we may recognise

1 Painful spasm in the unparalysed or partly paralysed antagonists of completely paralysed muscles

2 Pain due to stretching of the posterior muscles—calves, hamstrings, and erectores spinæ—which are in spasm as part of the meningeal reaction This is not necessarily related to the onset of paralysis and is often most severe in cases which ultimately recover completely

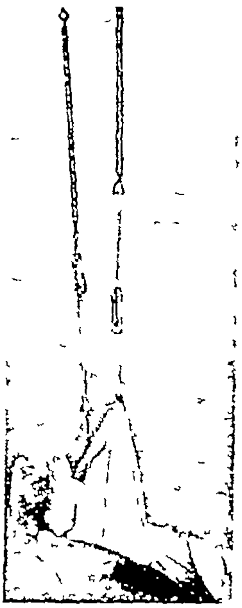

Fig 2—Sling-and spring suspension from ceiling for gross paralysis of lower limbs in an adult.

3 Pain arising from the joints and their ligaments, and continuing even when spasm has been relaxed by drugs

4 Secondary pain due to overstrain of ligaments from the faulty position of paralysed limbs

5 Perhaps pain of central origin *and due to inflammation* in the sensory roots and ganglia Against this, however, is the fact that the patient rarely feels pain while lying perfectly still and undisturbed.

Spasm embraces

1 Spasm of the antagonists of completely or partly paralysed muscles

2 Primary meningitic spasm of calves and hamstrings, not necessarily related to paralysis

3 A much rarer form occurring during the progress of a limb muscle to complete paralysis We have had only a few cases, always in the quadriceps, where the muscle, capable of little or no active contraction, feels indurated to the touch and gives the sensation of fine fibrillary contractions for 24-48 hours before it becomes soft and functionless

However troublesome pain and spasm may be, they must not be allowed to obstruct daily passive movements. Firmness on the part of the physiotherapist is essential —a single decisive movement *may stretch the hamstrings* where more timid attempts fail—but it may be necessary to obtain assistance from drugs

Curare in sufficient dosage will usually relieve most of the spasm and has been vigorously recommended by Dr N S Ransohoff in New Jersey (*Lancet* 1948), but it does not simultaneously relieve the pain Even when the patient has been reduced to flaccidity, movement may remain agonising, and therefore we cannot regard curare as a suitable aid to therapy, apart from its undoubted value in relieving urinary retention due to spasm of the sphincters

'*Priscol*' has been reported on with enthusiasm by Smith *et al* (1950) in New York, but we have not found it of great value, and its effects are less dramatic than those of curare

Intravenous *procaine*, in our hands, has also had only an uncertain effect on pain and spasm, even in large dosage

The veins of small children are not always suited to the administration of these drugs, and the well established relation between intramuscular injections and the site of paralysis in closely following poliomyelitis is a contra-indication to intramuscular injections in the acute phase of the disease We prefer not to give them except into the muscles of completely flail limbs

However, the problem of really serious pain and spasm is not a serious one in this country, where poliomyelitis seems in this respect to differ from the American variety Thus Smith et al. found priscol valuable because it relieved the nurses of the arduous duty of renewing the hot packs in most of his cases Not more than perhaps 10% of our cases are troubled with really severe pain and spasm, and by far the best method of obtaining full motion in such cases is under temporary analgesia-anæsthesia induced with rectal thiopentone or with gas and oxygen Patients in respirators must still be taken out daily for treatment while breathing is maintained with an anæsthetic machine, and this is often just the type of case with the greatest pain

TREATMENT DURING RECOVERY

Once the painful stage is over, or not too troublesome, all the children have daily massage and mobilisation for the back, where rigidity may develop even in non-paralytic cases As recovery proceeds, passive movements give way to assisted active movements, and then to progressively more active exercises against resistance Whenever there is gross paralysis of the lower limbs, return of power in the gluteal and adductor groups is encouraged by sling and spring suspension from eyelet hooks screwed 18 in apart in the ceiling over the bed (fig 2), in the case of young children, these can be attached to double Balkan beams slung across the cot-rails (fig 3) Patients on slings must be taught to perform single deliberate movements with a pause between each phase, or the mere recoil inertia of the apparatus will give the illusion of recovering power The heels need be only just clear of the bed, and then the glutei maximi muscles can be exercised by forcing the feet down on the covers, if these muscles are too weak for this, the patient is turned on his face in the slings for part of the day, so that the springs assist the movement of hyper-extension at the hips As the glutei medii recover, the apparatus can be loaded against them by incorporating a cross spring to make abduction more difficult (fig 2) or by weighting the slings with shot It is important that the exercises should not progress in activity too rapidly, but it is also important to keep slightly ahead of the patient's capacity The sling and springs can also be used for the shoulder if fixed to the overhead bed pulley when the patient has reached the three pillow stage (fig 4)

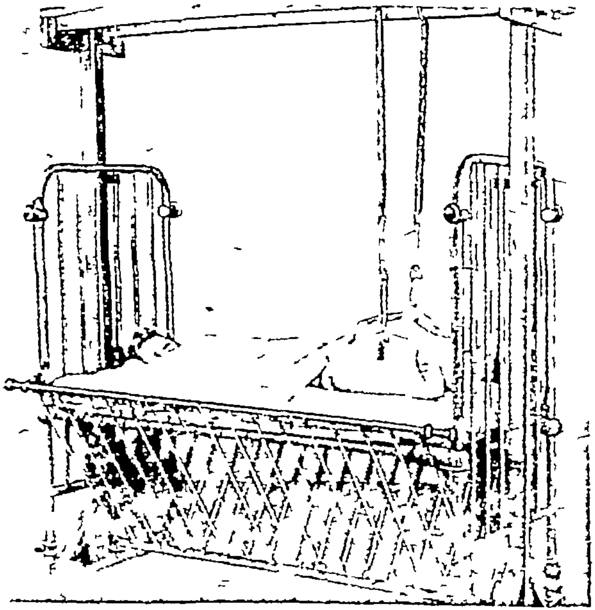

Fig 3—Sling-and-spring suspension from Balkan beams for gross paralysis of lower limbs in a child.

INSTRUMENTATION

Future needs for surgical appliances are foreseen as far as possible, and these are ordered well in advance We prefer to tend to over instrumentation and then are prepared to shed part or all of the appliance when it becomes clear that this is safe The patient who is beginning to get up and about, whether or not with the help of a calliper, is watched more carefully, and charted more often, to ensure that trunk and hip muscles do not deteriorate under the strain If they are evidently holding their own, he is sent home after a few weeks When patients require tendon transplantation or foot-stabilisation operations they are admitted to the surgical wards of this or an associated local hospital, and after operation they return to the unit in plaster

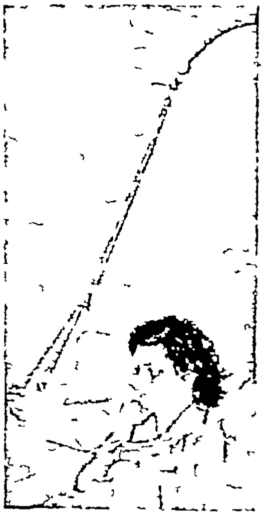

Fig 4—Sling-and-spring suspension from bed pulley for paralysis of shoulder muscles.

It is important to watch even apparently non paralytic patients for a time in the follow up clinic, because previously undiscovered weaknesses of spinal and trunk muscles may not become obvious for some time Since this hospital draws its poliomyelitis cases largely from a geographically small but densely populated sector of London, many patients live within quite a short distance We have found it an enormous advantage to be able to follow these cases through in close touch with parents and home conditions, it is possible to train them in hospital to deal with replicas of the physical difficulties they will have to surmount at home, to prevent any overfatigue—or overprotection—in the family circle, and to watch over rehabilitation and return to work in consultation with the local resettlement authorities

Possibilities

The only reasonable outlook for the therapist in polio myelitis is one of sober pessimism No one can yet cure the disease, and it has been said that the end result after ten years is the same whatever treatment—or if no treatment—is given. While this saying may be true in so far as the sum total of *potential* recovery is concerned, it overlooks the fact that even this potential will not be realised if careless management allows contracture and fatigue to prevent the orderly development of what muscle power exists It is common for a missed case not to be admitted to hospital until some weeks after the acute stage, when prompt improvement occurs in muscle groups relieved from overstrain Would such improvement have taken place without treatment?

However pessimistic in private, we must be uniformly optimistic in encouraging the patient to make the fullest use of what he possesses, and should err in the direction of the mildest of bullying to prevent self pity and keep his capacities fully extended It is a mistake, for instance, to order a wheel-chair at an early stage for any young adult before he has explored to the limit his capacity to get about unaided and has found a job

The outlook in poliomyelitis is dominated by the rapid development of irreversible changes produced by the virus in the anterior-horn cells of the cord Though specific antibiotics may well be discovered, there will still remain the problem of diagnosing poliomyelitis and exhibiting the antibiotic in the few hours or days before these permanent changes take place In the classical description, the paralysis of this disease is fully fledged at the outset, but we have been greatly impressed by the number of cases which enter hospital without any paralysis at all, or only mild paresis, and then go steadily downhill during the next few days Apart from actual death of neurones from virus toxicity, at least part of the damage must be due to inflammation within the cord —the perivascular cuffing, œdema, and glial infiltration These must be potentially reversible, and Steindler (1947) goes so far as to postulate the essential reversibility of the lesions in the anterior horn cells "Up to a certain point the changes seen in these cells must be reversible, just as the inflammatory glial infiltration and the perivascular lymphocytic exudates are reversible"

This seems to offer hope for the future, now that we are beginning to learn how to control the body's response to injury It was natural to use 'Cortisone' and adrenocorticotropic hormone (A C T H) in the hope of arresting these disabling vascular responses to infection within the cord, since these substances act to a considerable extent by preventing just this defence reaction in other tissues Though a very thorough trial of A C T H by Coriell et al (1950) showed no improvement whatever in paralysis or in mortality over untreated controls and though cortisone produced a severe exacerbation of experimental infections in animals (Schwartzman 1951), it may still prove somehow possible to reverse the inflammation within the cord, and work should continue along these lines

It is a great pleasure for me to acknowledge the devoted care my patients have received from Miss May Cooke, C S P, physiotherapist in charge because the skill and personality of the physiotherapist are far more important in poliomyelitis than anything the doctor can do Both of us have had every possible help and encouragement from Dr John Armstrong, physician superintendent of Brook Hospital

MEDICAL AUXILIARIES IN THE N H S

REPORTS OF THE COPE COMMITTEES

Two years ago the Minister of Health and the Secretary of State for Scotland set up eight related committees to consider the supply and demand, training, and qualifications of the following groups working in the National Health Service

Almoners	Occupational therapists
Chiropodists	Physiotherapists (including remedial gymnasts)
Dietitians	Radiographers
Medical laboratory technicians	Speech therapists

The majority of members agreed to accept the term 'medical auxiliaries" as a designation for these groups, accepting the view that "however different their duties may be, all medical auxiliaries in the National Health Service have this in common—they work for the benefit of the patient under the direct or indirect supervision of the doctor"

The chairman (Mr V Zachary Cope, F R C S) and two members (Dr G A Clark of the Ministry of Health, and Mr A B Taylor of the Department of Health for Scotland) were common to all eight committees, and with the secretary (Mr T C L Nicole) they have prepared the main report on "matters common to all types of medical auxiliary service"[1] This is followed by the reports of the eight committees Nearly all the members of these committees have approved the main report as well as their own, but there are three minority reports expressing dissent

SUPPLY AND DEMAND

In the main report a distinction is made between "need" and "demand" By "need" is meant the numbers required by the N H S to give the public a full service in all parts of the country "Demand," on the other hand, is defined as the number of vacancies that employing authorities are likely to seek to fill at present or, say, within the next five years

Just as many different factors may limit demand, many other factors may limit supply Most entrants to the medical auxiliary services are drawn from those who pass the School Certificate or some equivalent examination From this pool come nearly all entrants to the professions and a wide range of executives, secretaries, and technical staff in the public services and businesses Any gain in recruitment in one auxiliary service is likely to be made at the expense of recruitment in another auxiliary service—or in some other occupation which may be of national importance and already undermanned, such as teaching or nursing

In some of the medical auxiliary services demand exceeds supply, and the professional associations may seek, severally and independently, to expand their ranks in order to meet it Such competition may defeat itself, and there should therefore be some means of coordinating the relation of supply to demand over the whole medical auxiliary field "The problem of supply is not one of meeting *all* requirements of all kinds as soon as possible, but of advising on a balanced programme of recruitment over a period of time so as to try to spread the available man power over the medical auxiliary services to the best advantage"

Though salaries were not mentioned in the terms of reference, the report says that men and women entering the auxiliary services should be assured of salaries and, so far as possible, of prospects of promotion, similar to those of occupations with comparable standards of training In particular "account should be taken of the effect of salary scales upon recruitment of both men and women when the supply is below the demand"

TRAINING

Some of the services covered fall into groups, either because several types of auxiliaries work together as a team under a hospital consultant or because of affinities in the work done Thus on the one hand there is a "rehabilitation group" consisting of physiotherapists, occupational therapists, and remedial gymnasts, and on the other there is a medical social group which includes almoners with others (outside the terms of reference) such as psychiatric social workers Dietitians and chiropodists cannot readily be grouped with others

The committees sympathise with the view that there should be some common training in basic sciences for some auxiliaries, or at least for those in each distinguishable group, but they note practical difficulties For example, in certain basic sciences, such as anatomy and physiology, the same syllabus will not serve equally well for the speech therapist, the chiropodist, the radiographer, and the physiotherapist Nevertheless the possibility of a common basic course should be kept in mind, especially when new training schools are being set up And, whether attendance at common lectures is possible or not, students should certainly be given the opportunity of learning about work in related services

---

[1] Reports of the Committees on Medical Auxiliaries Cmd 8188 H.M Stationery Office 1951 Pp 227 5s

Continuing machinery is needed for joint consultation on the coordination of training wherever such cooordination seems desirable "we do not think that such coördination should be left entirely, as at present, to the initiative of individual professional associations of medical auxiliaries" Machinery is also needed to ensure that training keeps pace with advances in medical thought and practice Additional types of medical auxiliaries may seek recognition, and problems of demarcation of function may arise, in which case there must be machinery for giving an authoritative decision

QUALIFICATION

In the words of the Medical Act 1858, "it is expedient that persons requiring medical aid shall be enabled to distinguish qualified from unqualified practitioners" Similarly, it seems expedient that, as regards the medical auxiliary services, employing authorities should be enabled to distinguish between those qualified and those unqualified to work in the N H S

In the absence of any generally accepted or official scheme of training, groups of able and far sighted auxiliaries formed their own professional associations, which started training courses or sought to coordinate the content and standards of courses Often associations grew up in different parts of the country, sometimes with different views on the content of training In most cases one professional body has emerged for each type of auxiliary service, but for some services there are, in addition to the main recognised bodies, still a number of bodies professing to grant certificates of competence

Professional associations usually maintain a register of persons who have obtained the certificate or diploma of the association and who comply with the ethical standards it lays down These registers, however, have their limitations They have been useful, but only to those who have been able to assess their reliability

Before the war the British Medical Association set up an independent Board of Registration of Medical Auxiliaries, whose main object was to maintain and publish a register or registers of persons qualified to practise medical auxiliary work The qualifying bodies that have been recognised by the board are the Association of Dispensing Opticians, the British Dietetic Association, the British Orthoptic Society, the Chartered Society of Physiotherapy, the College of Speech Therapists, the Society of Chiropodists, and the Society of Radiographers In 1944 the Chartered Society of Physiotherapy resigned from the board, whose registers now contain about six thousand names The board has done good work in raising the status of the groups of medical auxiliaries on its registers, but by its nature it suffers certain handicaps It is a voluntary body, dependent for its existence on other voluntary bodies and on subscriptions voluntarily given, and its registers appear to be no more than reproductions of the registers of the constituent professional associations, with the omission of the names of those who do not apply to it for registration It has exercised care in the approval of training schools, but the inspections made on its behalf have in the main been limited to visits before recognition "We understand that routine visits to schools and examinations are now to be made, but, in the matter of effecting improvements the Board, as a voluntary body, will find itself at a disadvantage"

The report concludes that a system of statutory registration of medical auxiliaries is desirable to ensure that those employed in the N H S are properly qualified There should be a separate register for each auxiliary service, and these should be open to all medical auxiliaries qualified for employment in the N H S, whether they are already employed therein or not

At present any recognition of training schools is undertaken by the professional associations concerned "the final decision is taken by a *professional* association that is representative essentially of the *auxiliary* service concerned." Such arrangements are open to some objection on principle The associations are—properly—concerned with the standards of competence of their members, but for the maintenance of standards of competence within the N H S the statutory responsibility rests with the two Ministers Though the associations should continue with their educational activities, they should not have undivided and final responsibility for recognition of training schools and examinations for N H S purposes

A NEW COUNCIL ?

It could be left to the Ministers to take the necessary decisions on the advice of their departments. But non-departmental machinery can be established on a more representative basis and is likely to command more general acceptance

The committee considered whether the professional associations themselves, or the Board of Registration of Medical Auxiliaries, might undertake the tasks outlined But "it is no part of the function of a professional association or of the Board to attempt to maintain that broad view of the whole field of the medical auxiliary services in the National Health Service without which most of the tasks cannot be performed" Furthermore, the associations and the board are interested in all qualified persons, whether working in the N H S or outside it, and whether at home or abroad This range of view is unnecessarily wide for purposes of the N H S "Apart from these considerations, Parliament has from time to time taken the view that the function of the registration of professional qualifications should be separated from the protection of the interests of the members of that profession, and this protective function is an essential element in the work of a professional association, although not necessarily the most important"

A second suggestion was that the machinery should be based on the natural grouping of the medical auxiliary services, and there should be two, three, or even four "group councils" so constituted as to cover the whole medical auxiliary field To this the main report objects that

> Independent group councils would be unable to perform all the tasks that we have said will have to be undertaken. The relation of supply and demand has to be reviewed from time to time and correlated over the *whole* medical auxiliary field Unless this is done, there will be a risk of competition for recruits between groups of medical auxiliaries, just as there is a risk of competition at present between individual auxiliary professions If a demarcation problem arises between services in separate groups where will an impartial and authoritative decision be obtained? Furthermore, it would be difficult to devise machinery for admitting new types of auxiliary service to registration. Which group council would consider an application from a professional association? Who is to decide this question in the event of a difference of opinion? How and by whom are new group councils to be established if there should be a need for them? A statutory system of independent group councils seems to us to be too much lacking in flexibility for long term needs'

The conclusion was reached that only a single council would provide the necessary machinery

> 'We admit, and indeed we have stressed, the diversity of the medical auxiliary services We attach much more importance however, to the underlying unity in these services. In the National Health Service all medical auxiliaries are

united in the sense that they all assist the doctor and all have as their objective the welfare of the patient In these two respects they are all on common ground A single council seems to us, therefore, not only to be right in principle, but to provide a better means than a series of independent group councils of promoting a sense of common service among medical auxiliaries and of emphasizing the common objects of medical auxiliary work. If a council is to command respect in the medical and medical auxiliary professions and among the general public, and if its advice is to be of real value to the Ministers, it must be free from any sectionalism We feel that it might be difficult to obtain suitable members able and willing to give this kind of public service unless for a council with a wide field in which to operate Our strongest objection to a system of independent group councils, indeed, is that the medical auxiliary services in the National Health *Service deserve something better* "

Following the precedent of bodies concerned with education and registration in medicine, architecture, and law, the main report proposes a single statutory council of limited size, advised and assisted by professional committees It would be called the Council for the Medical Auxiliary Services in the National Health Service, and in order to cover England, Wales, and Scotland it would be under the ægis of the Privy Council The members might be

Four appointed by the Privy Council of whom one shall be from Scotland and one shall be designated as chairman

Three appointed jointly by the Minister of Health and the Secretary of State for Scotland

Two appointed by the Royal College of Physicians of London

Two appointed by the Royal College of Surgeons of England

One appointed by the Royal College of Obstetricians and Gynæcologists

Two appointed jointly by the Royal College of Physicians of Edinburgh the Royal College of Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow

One appointed by the General Medical Council

Six medical auxiliary members elected by the vice-chairmen of the professional committees from among their own number

They would retire every four years and would not be eligible for reappointment for two years

Each professional committee would as a rule be concerned with a single auxiliary service, and would consist of medical, medical auxiliary, and other members, the medical auxiliary members having a majority (not exceeding, say, three fifths) "It must be a body of experts in its particular field" Its chairman would be appointed by the council, preferably from among the council's members, but the committee would elect its own vice chairman, who would be a medical auxiliary As shown above, the vice chairmen would form an "electoral college" electing six of their number to the council. Having framed its policy, with the advice of the professional committees, the council would rely on the committees to carry it out For example, though the council would have final responsibility for registration and would be the arbiter in the determination of disputes, the committee would have to maintain the appropriate register and implement decisions

Neither the council nor its committees would have power to control the professional associations, which would continue the work they have chosen for themselves under their own constitutions "In particular, we think that it would be unsound for a central Council to attempt either to conduct training courses or examinations" Many associations have members working outside the N H S and would wish to maintain their own registers in order to cover all forms of employment

The council is regarded as essentially an administrative body, dependent on professional committees for information, advice, and executive assistance, and consisting of men and women experienced in judging impartially on evidence laid before them Since Scottish problems and systems differ in some respects, it would be required by statute to meet in Scotland at suitable intervals

As it is important that the registers should contain an up to date record of persons in, or qualified for, employment in the N H S, together with up-to-date information about qualifications, place of residence, and employment, it would be unsatisfactory for the council to take over any of the lists of names in the registers of professional associations All who seek registration by the council will have to make application individually

PROVISION OF TRAINING

At present there is considerable variety in the arrangements for training medical auxiliaries, and considerable variation in the method of financing students The Ministers might themselves be wholly responsible for the provision of training and for financial aid, but this arrangement appears inappropriate, because many medical auxiliaries may not wish to work in the N H S Alternatively, the Ministers might be responsible only for providing the clinical facilities necessary for training; the students would find the money, and would look for assistance to the local education authorities This arrangement is regarded as appropriate, except where this training approximates to an apprenticeship as in the case of medical laboratory technicians

If the Ministers are not to be responsible for more than the provision of clinical facilities, "it would appear that the institutions giving the training should themselves be independent of the hospitals which are under the direct control of the Ministers They would need, therefore, as their governing bodies, organisations which would represent all the interests concerned in training We are aware that the general and immediate adoption of this principle might cause undue disturbance, but we consider that new governing bodies of this kind should be adopted for any new schools set up"

MINORITY REPORTS

Two of the three minority reports favour alternative machinery for registration The first wishes to see a statutory registration board established for each profession If necessary, an advisory and coördinating body, to be called the Council for Non medical Professional and Technical Staff in Health Services, could be set up as well This council would have only eight members, not more than two of whom should be medical The signatories of this report regard the term "medical auxiliary" as inapplicable to their professions

The second report recommends grouping of some of the professions A Council for Physical Therapy in the N H S would maintain registers of physiotherapists, occupational therapists, and remedial gymnasts This council, with twenty five members, would be aided by professional committees

The third minority report dissociates itself from the second on the ground that it "gives unbalanced emphasis to the work of the Occupational Therapists in the physical field and completely disregards the psychological aspects of occupational therapy" It also dissents at various points from the report on occupational therapy

REPORTS OF INDIVIDUAL COMMITTEES

Almoners

The evidence suggests that the hospital service in England and Wales alone probably needs 2500–3000 almoners to provide a full service and in Scotland about 500 The probable demand over the next five years is likely to be more limited, but is at least 150 almoners each year The students in training "are hardly enough to make good the wastage and it is evident that unless recruitment is considerably increased it will be impossible to meet even the existing and immediate demands " Publicity in schools and financial assistance to students are recommended as aids to recruitment, but it is recognised that there are too few social science students in the universities to meet the requirements of all the professions for which this training is the basis The training and qualification given by the Institute of Almoners are suitable for almoners in the N H S

Chiropodists

Only 7 5% of the hospitals have so far appointed chiropodists As soon as possible there should be chiropodists at every general hospital and in certain hospitals and clinics, and local authorities should be enabled to provide chiropody in the N H S The training and qualifications of the Society of Chiropodists are suitable Part-time training cannot equal full-time training in value

Dietitians

In December, 1949, only 139 dietitians had been appointed among 2600 hospitals and convalescent homes in the N H S in England and Wales Each hospital group will need one or more Members of the British Dietetic Association are fitted for employment in the N H S

Medical Laboratory Technicians

At the end of 1949, 1602 medical laboratory technicians were employed at hospitals in the N H S in England and Wales and 180 in Scotland At the same date there were 1898 students in training At present the supply generally meets the demand but there are local shortages, particularly of trained technicians The training and qualifications of the Institute of Medical Laboratory Technology are generally suitable

Occupational Therapists

About 3000 occupational therapists are needed for the N H S The number actually employed is 980 Financial restrictions, &c , are likely to prevent the demand from rising to any extent for some time Occupational therapists holding the diploma of the Association of Occupational Therapists or that approved by the Scottish Association of Occupational Therapists are fitted for employment in the N H.S

Physiotherapists

A year ago there were just over 4000 physiotherapists working whole-time or part-time in the National Health Service in the United Kingdom, and some 1500 more will be required The present output of trained physiotherapists is over 500 a year and it should be possible to maintain the present numbers in the N H S and gradually build up to the full demand Supply and demand are fairly evenly balanced Physiotherapists at present registered with the Chartered Society of Physiotherapy and the Faculty of Physiotherapists are suitable for employment in the N H S The general direction of studies in each school should be in the hands of a medical practitioner, preferably a specialist in physical medicine, and facilities for the training of men should be increased Part-time training that is wholly in the hands of non-medical teachers and does not include any considerable amount of varied clinical experience is not adequate

Radiographers

The current output of students should suffice to meet the present demand The Ministers are invited to consider whether blind assistants could undertake dark-room work so as to relieve radiographers for their specialised duties Members of the Society of Radiographers are qualified for employment in the N H S Training should be given only in recognised schools able to provide both theoretical and practical training More men should be trained Students should pay for their training and, with the possible exception of some nurses, should not receive a salary

Speech Therapists

There are nearly 300 speech therapists practising in the United Kingdom, and at least 750 are needed both inside and outside the N H S Local education authorities and hospitals should work closely together so as to use the services of speech therapists as economically as possible Those holding the diploma of the College of Speech Therapists are suitable for employment in the N H.S

FREE MEDICAL CARE OF MOTHER AND CHILD IN EIRE

FROM OUR DUBLIN CORRESPONDENT

THE crisis over the scheme for free care of mothers and children in Eire has now been resolved by the resignation of the minister for health, Dr N C Browne At the end of last month[1] there seemed little prospect of any concessions by the minister to meet the objections of the Irish Medical Association , nor, in fact, were any made by him Ecclesiastical authorities also objected, on moral grounds, to certain features of the scheme, though they raised no objections to the Social Welfare Bill—very much wider in its scope of social benefits, but on a contributory basis—now before the Dail.

Only in recent weeks did it become clear that well over 80% of the medical profession were opposed to the scheme The only modification accepted by Dr Browne was that enabling general practitioners, as distinct from dispensary doctors, to join it should they wish On April 6, the government instructed Dr Browne to draw up proposals for a Mother and Child Scheme free from the features to which exception had been taken He preferred to abide by his own scheme, and resigned on April 11

Replying in the Dail to an attack by Dr Browne on his erstwhile cabinet colleagues, Mr J A Costello, the prime minister, said

> " Every time there was any suggestion of an attempt to meet the minister for health the people who gave in and said that they were willing to come and consult were the medical profession, and every time they were turned down with contumely by the minister for health I feel it my duty to pay tribute to these men who have done everything they can to see that the mothers and children of this country get a scheme "

Mr Costello, who enjoys the full confidence of the profession, has himself temporarily taken over the ministry of health, and there seems now no reason why negotiations for a new scheme, which have already started, should not proceed in an atmosphere of mutual good will In Eire, as in other countries, some means will have to be found of assisting the middle income group to meet the cost of present-day medicine, and any new scheme is sure to provide for this group

Medicine and the Law

What is " Therapeutic " Treatment ?

THE claim of the Royal Victoria Hospital, Dundee, to remain outside nationalisation involved the Court of Session in a discussion of the word " therapeutic " If the treatment afforded was not of a therapeutic character, the hospital might escape being taken over under the National Health Service (Scotland) Act

For the hospital it was contended that the meaning of the word was limited to treatment designed to cure As the patients were incurable cases and the treatment and nursing could do no more than alleviate their suffering, the measures taken could not be " therapeutic " On the other side it was argued that the word applied not only to curative treatment but also to measures taken to relieve symptoms and alleviate pain

After hearing the opinions of medical witnesses, and after recourse to such guidance as dictionaries afford, Lord Blades held that the remedial treatment of disease included the associated relief of suffering He was unable to apply the test of curability or incurability for the purpose of deciding whether measures to combat illness, relieve symptoms, or alleviate suffering were or were not therapeutic The main purpose of the hospital, he said, was therapeutic It did not come within an exception provided by the statute It was a voluntary hospital within the meaning of the Act, and the Secretary of State for Scotland was entitled to remove it from private hands

A Running Commentary by Peripatetic Correspondents

The signs I find in chests, and plot
So skilfully on diagrams,
Too frequently, alas, are not
Apparent in the skiagrams

Too seldom does the screen disclose
Nor all that barium reveal
The ulcers which I diagnose,
The epigastric lumps I feel

Proof positive, this seems to me,
—*Proof stark and undeniable*—
That radiology must be
Extremely unreliable

* * *

Spring cleaning is about to begin Most of us get used to the discomforts of the weekly turn out of one room at a time, but at this season the process is applied to every room at once, and the only thing is to take all the meals one can at the club and spend one's free time anywhere but in the house, preferably gardening, so as to be within hail when something has to be lifted To complicate the issue in our house the decorators' buckets and steps are always stored in the bathroom Surely this spring cleaning business shouldn't be needed any longer, when we have electrical cleaning devices which do more good in a routine daily session than a complete turn out did of yore? Besides the modern household either has electric or gas fires or no fuel for fires at all, so there can't be anything like as much dust But spring cleaning has become a tradition, like wearing something new at Easter So we may as well resign ourselves to a week or two every year when nothing is where it used to be and there's only the stairs to sit on

* * *

When I qualified, 20 odd years ago, we were expected to know only just enough chemistry to prevent the corks blowing straight out of any bottles we dispensed $-NaHCO_3 + HCl$ that kind of thing But this certainly wouldn't satisfy a modern examiner, and I am beginning to wonder whether we inorganic G P s ought to be allowed to go on prescribing the newer-fangled drugs when we couldn't tell their composition from Adam's if we saw the two side by side Most of us, I suppose, as the years go by, merely lean more heavily on our friend the pharmacist—and *hinc illæ lacrimæ*

In our traditional daily chat I asked our pharmacist if, when I prescribe "phenobarbitone tablets," he dispenses sodium phenobarb or plain phenobarb You'd have thought I'd asked how much hashish he was selling, or something even more shocking When at last he had recovered enough to speak he told me "Plain phenobarbitone, of course, Doctor" "But," said I, putting my foot right in it, "I order them at random, sometimes everybody gets the sodium stuff and sometimes the other, just by chance That means I've ordered some people twice as much hypnotic, or half as much, as I intended" Only then did the full force of my ignorance strike him "The molecular weight of phenobarb being 232," he explained pityingly, "and sodium's atomic weight 23, tacking an atom of sodium on each molecule makes your 1-grain tablet contain about nine-tenths of a grain of phenobarb And as it will be much more soluble, your patient will really find it a good deal stronger hypnotic Good morning"

I see now that the Higher Certificate examiners knew their stuff when they endorsed my certificate "NOT Organic Chemistry"

* * *

It is high time that our Planners turned their attention to pay and status in orchestras All the conductor need possess is a nodding acquaintance with the range of orchestral instruments, an ability to interpret a score, and the nerve to stand up in front of the audience for an hour or two waving a stick in a purposeful manner Ask him to play among the second fiddles, or even to deputise for the tympanist, and he will be out of a job in less time than Menuhin takes to play an A pizzicato Yet it is the conductor who gets all the kudos and most of the cash An obvious effect of this cult of the jack-of-all-trades is to produce few real masters of any All the most promising students of music have conductorship as their goal Why should they spend years learning to beat the triangle with absolute precision when in the end they cannot hope even to see their names on the programme in 6-point italics (*J Jones*) as leaders?

* * *

When the influenza epidemic was at its height one of my colleagues was rung up during his evening surgery and an apologetic voice asked if he could possibly manage a visit that day The caller had fallen in the bathroom that morning, had managed to crawl to his bedroom, and had been lying there ever since, unable to put his foot to the ground He thought his leg was broken He was most emphatic that he was a private patient, and did not want to be treated under the N H S My friend went round and found an irate old gentleman lying on his bed with a Potts fracture When first aid measures had been applied, the patient became quite chatty It seemed that he had just moved into the district, and he had spent all day ringing up the local doctors, but when he told them he was not an N H,S patient, each one in turn had flatly refused to visit him—no time to call on private patients was the reply "The old order changeth"

* * *

The art of lecturing is generally accepted as moribund if not actually dead, so it was an unusual experience to hear a lecturer speak for an hour on a fairly complex subject without a single note and without a moment's hesitation or uncertainty Equally surprising to me was the sparsity of the audience! The lecture had, I understood, been well advertised, the subject was one likely to combine welcome instruction with an element of entertainment, and yet when, arriving late, I feared not to find even standing room, I had a whole row of chairs to myself On the other hand, many of the "lectures" I attend consist of the most prosaic textbook material read rapidly to an audience that fills the hall to capacity There must be a reason for this contrast in attendances Presumably some lectures are announced in a way that appeals to the popular taste, some, I dare say, are announced so obscurely that nobody hears of them until afterwards But it does seem strange that we flock to hear somebody read to us what we could very well have read for ourselves at our leisure Maybe this is one more evidence of the persistence of the child in us every child loves being read to, especially if the story is one he knows well—and woe betide the reader who introduces some unorthodox deviation from the familiar text

* * *

The junior nurse was taking the particulars of a new patient, a wizened retiring little man She got his name, address, age, and sex without difficulty, but when she asked for his next of kin he answered "None" "Surely you must have *some relations*?" said the nurse But the little man wouldn't be moved "No," he replied, "Not at all." "Well," said the nurse, beginning to get worried, "we must put someone down What about the lady who came with you?", for a large bejewelled woman had accompanied the little man to the door of the ward. "She'll do," the patient replied, "She's my mistress." This took the nurse's breath away (she was very junior), but in the end she said rather shakily, "We really can't put that down, you know, shall I say sister, or cousin perhaps, instead?" The little man seemed shocked "No," he insisted, "she's my mistress" Then the nurse had a brainwave "I know, I'll write 'friend'" "No," said the little man, polite but firm, "as I told you before she's my mistress—I work for her"

And so guileless was the little man that when the nurse had been outside to powder her nose they went quietly on with the next question.

Aphorism of the Week

Let sleeping tubercle lie

Letters to the Editor

THE ECONOMIC VALUE OF THE DOCTOR

SIR,—The March 24 issue of your journal has just reached here with Dr Ffrangcon Roberts's stimulating discussion of this subject May I suggest that, in addition to the influence of ancillary personnel in medical practice, another factor is of perhaps greater importance in the attitude of the laity toward our profession. That factor, perhaps better seen in the United States, is the ever lessening gap between the educated layman and the physician

Formerly, with a low state of formal education in the general population, the physician's training widely separated him from the laity Today, with secondary schooling almost the rule and college attendance common, the layman has advanced relatively more on the educational scale than the doctor Premedical and medical training now is largely technical with consequent neglect of the nurturing of the more subtle aspects of the personality of the physician It is this personality which genuinely distinguishes the doctor from those in other technical callings The present result is a medical "technician" who, when the technical veneer has been scratched, is appallingly like other "technicians", in short, he is basically a layman This professional personality inadequacy is well demonstrated in the average doctor's attitude toward death Death upsets him, and he either acts as if it does not exist, or else regards it as a vicious reflection on his technical skill. His behaviour toward, and at the performance of, necropsy is equally enlightening in exposing the present professional personality pattern

Perhaps the remedy for the status described by Dr Roberts lies in a revaluation of the role of the doctor so that he may be more than a therapeutic technician among other technicians In a world advancing toward calamity by a series of technical competitions, I fear this revaluation is impossible

METHONIUM COMPOUNDS IN HYPERTENSION

SIR,—The experience in this clinic of hexamethonium in the treatment of hypertension confirms that of other investigators, particularly Professor Smirk and his co workers, in the following respects (1) if properly administered C6 appears to be an effective agent for reducing blood pressure in the majority of cases, including those with malignant hypertension, (2) oral administration is not so reliable as parenteral, and (3) the patient or a member of the family can be taught to administer the injections and record the blood pressure in the home, thus making long term therapy feasible In addition, I would like to suggest certain practical points in management which we have found greatly increase the effectiveness of the drug and reduce the incidence of toxicity

When doses of C6 were repeated at 4 or 6 hour intervals we observed frequently the rapid development of "tolerance" so that increasing doses were without hypotensive effect However, if the doses were separated by 12 hour intervals the development of tolerance was delayed or prevented while an increased dose now produced an augmented hypotensive response Thus, an 8 or 12 hour dosage interval usually was far more effective than a 4 or 6 hour interval In certain patients the hypotensive response to C6 was not maintained beyond 6 hours, and in these cases various other hypotensive agents were tried in order to prevent the rise of blood pressure The most effective agent was l hydrazinophthalozine ('C5968,' Ciba) in doses of 50–150 mg administered orally midway between the doses of C6 By using such alternating therapy the wide swings of blood pressure frequently were avoided and tolerance to either drug usually was prevented

Profound hypotensive reactions with collapse occurred almost entirely only after the initial injection of C6, and during continued administration the reduction of blood pressure was more moderate These severe hypotensive reactions have been avoided since we have utilised the following technique for beginning therapy

With the patient propped up slightly in bed, C6 was injected intravenously at a rate of 1–2 mg of the ion per minute An assistant determined the blood pressure at intervals of 30 seconds in the opposite arm As soon as a significant reduction of blood pressure occurred the injection was halted temporarily until the blood pressure stabilised If the degree of hypotension was satisfactory the injection was stopped. If not the slow rate of administration was begun again and continued until the desired result was obtained If despite these precautions, the reduction of blood pressure was excessive it was easily corrected by raising the foot of the bed on 6 in. or 8 in. blocks and elevating and passively exercising the lower extremities Vasopressor agents, especially epinephrine, were unpredictable, and impressed us as being dangerous.

Having determined the initial effective dose, this amount was administered subcutaneously at 12-hour intervals If tolerance developed the dosage was raised progressively by increments of 5–10 mg During such continuous administration of C6 the most common side effect was constipation, and the most serious was paralytic ileus Since both of these undesirable effects apparently were due to parasympathetic blockade we have used the urethane of acetyl β methylcholine ('Urocholine,' Merck) in doses of 5–10 mg orally twice per day, along with laxatives such as mineral oil and magnesium hydroxide if necessary

SURGICAL TREATMENT OF MÉNIÈRE'S DISEASE

SIR,—In your annotation on this subject (April 7) you stated that "in at least some cases of this disease the essential lesion is an excessive amount of endolymph." If this is so, it is scarcely logical to perform sympathectomy (which should lead to an increased blood supply in the denervated area) for its relief However, sympathectomy may succeed for other reasons, or in sufferers with no excess of endolymph.

The assertion that the main sympathetic supply to the head and neck comes from D1 is perhaps over confident Fibres to the eye emerge at this level, but it is not safe to assume that all the preganglionic vasomotor and sudomotor fibres for the head also emerge at the same level. Brown Séquard, Claude Bernard, and other early workers in this field thought the vasomotor fibres emerged over a wider area, thus, Brown Séquard [1] reported that the sympathetic fibres to the blood vessels of the head come from the cord chiefly through the last cervical and first and second thoracic nerve roots More recent observers, such as Hyndman and Wolkin,[2] and Goetz,[3] have suggested that many, and perhaps even the majority, of the preganglionic vasomotor and sudomotor sympathetic fibres for the head and neck are found in the second thoracic nerve roots and that any more widespread outflow is through lower rather than higher nerve-roots Thus, assuming that sympathectomy is justifiable in some patients with Ménière's disease, the scope of the operation performed by Mr Passe and Mr Seymour could be defended on anatomical grounds

Guerrier [4] claimed that preganglionic fibres entering the vertebral plexus emerge through the lower cervical nerve roots, and he suggests they were not discovered earlier because of their deep situation and short course The vertebral plexus is regarded as the main source of sympathetic fibres accompanying the internal auditory artery and supplying the internal ear, and any fibres emerging in the lower cervical roots would escape in the sympathectomy under discussion, or in any preliminary trial injection of the stellate ganglion If section of the main preganglionic outflow through D2 and D3 does in fact interrupt pathways to the head, including the ear (as the surgeons claim), then Hyndman and Wolkin, and Goetz are more likely to be correct than Guerrier If so, this is yet another example of how surgical procedures may assist in anatomical localisation and hodology, and conversely it shows how apparently insignificant anatomical details may be of vital importance in determining correct and scientific treatment

GENERAL PRACTITIONER AND CONSULTANT

SIR,—There are readier means of raising the status and standard of the general practitioner than those suggested last week by Dr Robertson

If laboratory and radiological facilities were extended to general practitioners in all areas they would readily accept the responsibility of pursuing, where possible, a final diagnosis, and would thus have in the eyes of their patients greater authority

The opportunity for a closer acquaintance with modern medical thought can be provided in two ways firstly, by generous use in hospitals of general practitioners as clinical assistants, secondly, by the establishment of clinical societies based on general hospitals where the G P can demonstrate his cases before fellow practitioners and consultant colleagues

If the capitation fee were adequate there would be no desire by the G P to augment his income and certainly not from the sources suggested by Dr Robertson May I add that I still find consultants readily approachable and prepared to lend an ear to the G P and to expand an opinion when requested

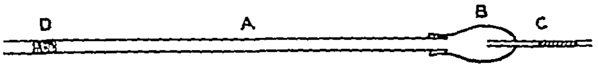
Beckenham Kent D I FINER

IMPROVISED VACCINE-LYMPH EJECTOR

SIR,—Quite a number of practitioners must have been called on to do vaccinations within recent weeks, and some may have been mildly irritated, as I was, by the problem of getting the lymph out of the capillary tube expeditiously and accurately I have found the following simple device, which takes only a very few minutes to make, practical in use and economical of lymph

A firmly fitting rubber bulb is pushed on one end of a glass tube about 8 in. long Into the other end of the tube a small pledget of cotton wool is pushed to act as a bacterial filter In the closed end of the bulb a very small hole is made with the red hot point of a pin. It may be that a black rubber bulb would not show up this hole so well as, say, a red rubber one The device is now ready for use

After the ends of the vaccine capillary tube have been broken off, one of them is pushed through the small hole in the bulb, which grips it (see figure) I have not yet encountered a capillary tube that a small hole in the rubber, made in the way suggested, will not grip I hold the device at the junction of the tube and bulb between the finger and thumb, the bulb can then be angled between the middle and ring fingers of the same hand (with the little finger resting on the patient's limb), so that the distal end of the capillary tube approaches the skin at a convenient angle By gently blowing down the other end of the tube one can extrude small neat drops from the capillary tube, and there is none of the troublesome back suction such as may occur with an ejector worked by finger pressure on a closed rubber bulb Usually four insertions can easily be made, with the help of this device, from one capillary tube It is possible to make up to five or six After a series of insertions the cotton wool can be removed and the glass tubing and bulb boiled



The ejector in use. A, glass tubing ; B, rubber bulb ; C vaccine-lymph tube and D cotton wool

I have been told that the Ministry of Health has never supported the idea of an ejector worked by blowing with the mouth, but I think that this criticism is overcome in my contrivance

Whitley Hospital, Coventry J F GALPINE.

FATE OF A GROUP

SIR,—The B B C broadcast (April 5) on "Taking Stock" of the National Health Service, once again advocated group practice and emphasised how a doctor in a group could follow some special line of his own to the benefit of the practice Almost every authority supports this view I should like to record what has happened in respect of our own group practice

In 1935 we reorganised our surgery accommodation. This involved a certain amount of building, valued today at over £7500, which gave an efficient place for a group to work When the National Health Service came into being the following happened

1 Our dispensary, where three qualified dispensers worked in a costly and well equipped department, became useless and we suffered a dead loss We received no compensation and were unable to sell hundreds of pounds' worth of drugs. The whole balance of the organisation of rooms was accordingly upset

2 Our surgical partner resigned from the firm to become a whole-time surgical consultant Had he not done so he would not have been able to retain his job on the staff of the local hospital

3 Our pædiatrician, by remaining in general practice, was unable to obtain a consultant appointment at the hospital. His hospital appointment was graded S H.M.O, but domiciliary consultations were allowed

4 One of our obstetricians, who had been doing all the emergency obstetrical work at a local authority maternity home, lost his job and was not even offered a G P clinic.

5 All fees and salaries for specialist work had to be cut out of income for the purpose of compensation, and we are to receive nothing at all for this source of income

Reading STANLEY ALCOCK.

MUNCHAUSEN'S SYNDROME

SIR,—The sparkling correspondence on this syndrome reminds me, even in distant Jerusalem, of my two favourite cases, which did the rounds of hospitals in general, and of L C C hospitals in particular, in the years 1936-40 (at least) They are probably very well known to a number of your readers

The first patient stated that he had repeated attacks of hæmoptysis, at intervals of a few weeks He used to appear in casualty late at night with his shirt and jacket covered with blood, but himself remarkably free from dyspnœa and anæmia On some occasions it was proved that the blood covering his clothes was not human blood, but occasionally human blood seemed to be admixed He would be admitted by casualty officers new to the hospital, and usually discharged himself at 6–7 A.M the next day after having had morphine and usually a good meal and a row with the nurses He usually succeeded in getting out before the senior medical officers, who knew him, began their rounds

The second patient, a much younger man, used to give a perfect history of recurrent attacks of appendicitis except that the pain was referred to the left side His abdomen showed operation scars After the senior people had been brought into consultation and he heard the surgeons talk of the possibility of operation, he would begin to insist very firmly that his appendix had been removed and that he was not going to submit to operation. He would then mention the words "transposition of the viscera." The casualty officer examined again and triumphantly proclaimed that the heart was on the right side. He was then brought into hospital and submitted to radiological and electrocardiographic examination, and transposition of the viscera was proudly demonstrated by the staff. He was then discharged. But it was too bad to get a call from another hospital in another quarter of London that he had entered there a few hours later with a similar syndrome. We discovered that this patient got board and lodging, comfort, and attention for most months of the year thanks to his masterly presentation of his alleged symptoms.

Hadassah Medical Organisation

ELI DAVIS
Director

SIR,—The correspondence following Dr. Asher's most interesting article of Feb. 10 indicates how prevalent this 'syndrome' is. By giving it this name, however, one might be induced to regard these people simply as tricksters, liars, and swindlers, without paying attention to the underlying psychopathology. These patients are invariably severe psychopaths, and their psychopathic personality requires treatment. The extravagant and often purposeless romancing related as facts is, of course, well known as pseudologia phantastica.

Wanstead Hospital
London, E.11
ERIC FRANKEL

PUBLICITY IN CANCER

SIR,—In his letter of March 24, Professor Russ rightly impeaches delay in seeking advice as the greatest handicap to the successful treatment of cancer, while at the same time he sees in this avoidable circumstance the greatest justification for campaigning for wider publicity in the fight against cancer. At any centre where large numbers of patients suffering from cancer are treated, the overwhelming importance of early diagnosis and treatment is all too clearly revealed. The difference in the results of treatment of early and late cases underlines the tragic effects of the patients' *own* delay in seeking advice. Fear, ignorance, and the thought that suffering is inevitable and cancer is incurable are only some of the reasons which hold the patient back until the condition has passed beyond hope of cure. And so the proportion of early cases seeking treatment remains pitifully small, although many thousands of lives could be saved if only the public could be convinced that cancer in the early stages can be cured.

To substantiate this claim Professor Russ deduces, from data supplied by the Christie Hospital and Holt Radium Institute, Manchester, two significant features: (1) an absence of improvement over a long period of years in the percentage of early cases seeking treatment; and (2) the enormous saving of lives which would follow if, through a more enlightened policy of campaign, more patients could be persuaded to seek advice early. Only in this way is the contrast between the numbers of early and late cases undergoing treatment ever likely to be lessened, and it might even become reversed.

On the supposition that the numbers of early and late cases treated at the Radium Institute, Manchester, during the periods specified were reversed, by means of a simple calculation Professor Russ shows that if 1000 patients suffering from cancer of the breast were treated by the methods now in use at that institute 454 would be alive after five years instead of 213—a saving of 241 extra lives. Applying the same formula to the cases treated for cancer of the uterine cervix the corresponding figures would be 630 alive after five years instead of 275—a saving of 355 extra lives. From a purely propaganda point of view this method of presenting the picture is so arresting as to make one wonder how far statistics obtained at other centres, and submitted to the same type of calculation, would support the urgency of the plea for a nation-wide attempt at breaking down the fear of cancer.

With this object I have submitted statistics relating to the radiation treatment of cancer of the breast and uterine cervix at the Marie Curie Hospital to the formula suggested by Professor Russ, and the following points emerge. Of patients treated for cancer of the breast during the period 1932–34, 19.3% were in stage I of the disease. After a lapse of about twelve years, little improvement had taken place, the proportion of stage I cases treated during 1946–48 being 22.6%. In the case of cancer of the uterus for the same years the proportion of cases in stage I increased from 5.5 to 27.7%. Though representing some advance this is far from being a satisfactory state of affairs, and any feeling of satisfaction is quickly dispelled when the position is viewed from the point of view of the lives that could be saved were the proportions of early and late cases reversed. For example, when the above-mentioned formula is applied to cases treated for cancer of the breast during the periods 1932–34 and 1946–48, 687 patients would be alive five years after treatment instead of 134—a saving of 553 extra lives out of a total of 1000. And in the case of cancer of the uterus, 640 patients would be alive five years after treatment instead of 146, a saving of 494 extra lives.

Such emphasis upon the number of *extra* lives which could be saved were patients to seek advice early instead of late should prove a powerful influence in the approach to a problem the gravity of which calls for a more vigorous effort than is known today in the education of the public concerning significant facts about cancer and its treatment.

WILL WE NEVER LEARN?

SIR,—Sir Heneage Ogilvie's letter of March 3 draws attention to one of the problems of a United Nations force, where there may be medical units of different nations in the field, and where forward surgery may be performed by surgeons of many different countries. This may lead to different standards and methods of surgical treatment.

The experiences learned in the late war are contained in the *Field Surgery Pocket Book*, a new edition of which was published in 1950 and is on sale (price 4*s.*) at the Stationery Office and through any bookseller. This is issued to our own medical officers and units in Korea, but similar publications are not perhaps available to all members of a United Nations force.

TREATMENT OF DEPRESSION

SIR,—In thanking you for your summary (March 31) of my contribution to the discussion on this subject at the Royal Society of Medicine, may I correct a mistake.

You state that I reported finding: (*a*) during psycho-analytic treatment of depressions, symptoms reminiscent of epilepsy, pointing to (*b*) an instinctive yearning of the patient for shock and convulsive treatment; and (*c*) that previous convulsive treatment was helpful to the progress of psycho-analytic treatment. In my paper I stated (*a*), did not state (*b*), and stated that I had no evidence for (*c*). With regard to (*c*) I said that of 67 depressives interviewed, 9 had had E.C.T. previously. All these were advised psycho-analysis; 5 accepted this treatment, and in none of these was it considered that the previous E.C.T. helped such treatment. In 1 patient it appeared that the memory of the painful electrical stimulus added to the complexity of the treatment.

London, S.W.7
W. CLIFFORD M. SCOTT

the vertebral plexus emerge through the lower cervical nerve roots, and he suggests they were not discovered earlier because of their deep situation and short course The vertebral plexus is regarded as the main source of sympathetic fibres accompanying the internal auditory artery and supplying the internal ear, and any fibres emerging in the lower cervical roots would escape in the sympathectomy under discussion, or in any preliminary trial injection of the stellate ganglion If section of the main preganglionic outflow through D2 and D3 does in fact interrupt pathways to the head, including the ear (as the surgeons claim), then Hyndman and Wolkin, and Goetz are more likely to be correct than Guerrier If so, this is yet another example of how surgical procedures may assist in anatomical localisation and hodology, and conversely it shows how apparently insignificant anatomical details may be of vital importance in determining correct and scientific treatment

Anatomy Department

GENERAL PRACTITIONER AND CONSULTANT

SIR,—There are readier means of raising the status and standard of the general practitioner than those suggested last week by Dr Robertson

If laboratory and radiological facilities were extended to general practitioners in all areas they would readily accept the responsibility of pursuing, where possible, a final diagnosis, and would thus have in the eyes of their patients greater authority

The opportunity for a closer acquaintance with modern medical thought can be provided in two ways firstly, by generous use in hospitals of general practitioners as clinical assistants, secondly, by the establishment of clinical societies based on general hospitals where the G P can demonstrate his cases before fellow practitioners and consultant colleagues

If the capitation fee were adequate there would be no desire by the G P to augment his income and certainly not from the sources suggested by Dr Robertson May I add that I still find consultants readily approachable and prepared to lend an ear to the G P and to expand an opinion when requested

Beckenham Kent D I FINER

IMPROVISED VACCINE-LYMPH EJECTOR

SIR,—Quite a number of practitioners must have been called on to do vaccinations within recent weeks, and some may have been mildly irritated, as I was, by the problem of getting the lymph out of the capillary tube expeditiously and accurately I have found the following simple device, which takes only a very few minutes to make, practical in use and economical of lymph

A firmly fitting rubber bulb is pushed on one end of a glass tube about 8 in long Into the other end of the tube a small pledget of cotton wool is pushed to act as a bacterial filter In the closed end of the bulb a very small hole is made with the red hot point of a pin. It may be that a black rubber bulb would not show up this hole so well as, say, a red rubber one The device is now ready for use

After the ends of the vaccine capillary tube have been broken off, one of them is pushed through the small hole in the bulb, which grips it (see figure) I have not yet encountered a capillary tube that a small hole in the rubber, made in the way suggested, will not grip I hold the device at the junction of the tube and bulb between the finger and thumb, the bulb can then be angled between the middle and ring fingers of the same hand (with the little finger resting on the patient's limb), so that the distal end of the capillary tub approaches the skin at a convenient angle By gentl blowing down the other end of the tube one can extrud small neat drops from the capillary tube, and there i none of the troublesome back suction such as may occu with an ejector worked by finger pressure on a closed rubber bulb Usually four insertions can easily be made, with the help of this device, from one capillary tube It is possible to make up to five or six After a serie of insertions the cotton wool can be removed and the glass tubing and bulb boiled

The ejector in use A, glass tubing, B, rubber bulb, C, vaccine lymph tube and D, cotton wool

I have been told that the Ministry of Health has never supported the idea of an ejector worked by blowing with the mouth, but I think that this criticism is overcome in my contrivance

SIZE OF MEDICAL SCHOOLS AND HOSPITALS

SIR,—In his thoughtful and illuminating article of March 17, on the Economic Value of the Doctor, Dr Ffrangcon Roberts uses the term "facultative audit" The need for inquiries of the kind he has in mind is urgent in still other directions The two questions I should like to see submitted to such a technique are (1) what is the optimum size of a medical school? and (2) what are the most economical sizes of the main varieties of hospital? Fairly extensive search of the literature has yielded no studies of the completeness that seems requisite

Years ago I started with the Calendar and the annual financial statement of my own medical school, to see whether my fear that we were too big could be justified on statistical grounds, but my knowledge of statistics proved insufficient An answer to the question could, however, be found from the data available Take a preclinical subject as an example—say physiology If the class is about 40, finance may dictate that the professor and one assistant must bear the whole burden of the teaching, and this has disadvantages when so wide a subject is covered It is asking a lot from a physiologist to be so interested in neurophysiology, metabolism, endocrinology, and the rest, that he will *teach* each division efficiently If the class is 220 the staff may comprise a professor, a reader, and seven lecturers or more, and specialisation becomes possible But the personal contact between staff and student is almost lost, while the physical limits of the department may necessitate the shift system for practical classes (The latter, as I know to my cost, imposes a burden on the staff which is far too heavy) What then is the best size of class? But wait, the answer must also take into consideration the most economical use of the department's space It must be heated, lighted, cleaned, and insured, and its capital value must be amortised What number of students is sufficient to justify the expense? At what point does overcrowding cause a loss of efficiency or an increase in cost through the need to improvise, or to provide duplicate apparatus? These are but a few examples of the multitude of variables with which such an inquiry would be concerned, but they are enough to show how complicated would be the integration of numbers of curves, often of opposite trends It would be a fascinating investigation, and I make a present of the idea to anyone who wants a novel thesis subject

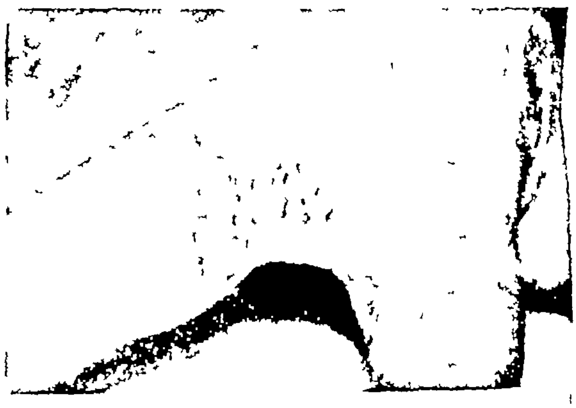
The same type of inquiry is applicable to the clinical side, though here the most important factors are the number of available beds, both general and special, and sometimes the amount of time taken in travelling to different hospitals Many estimates have been made of the best size of hospitals in different circumstances, but none I know of are based on a detailed actuarial and cost accounting basis parallel to the one suggested for medical school size We seem to have been waiting for the catalysis of Dr Roberts's phrase of the "facultative audit"

"CALCULUS"

PILONIDAL SINUS IN A BARBER

SIR,—I was interested in Mr Jenkins's description (March 31) of this condition Pilonidal sinus is usually regarded as a congenital disorder occurring in association with the spine, and presenting commonly as a dimple in the postanal region

Short hairs are regularly found penetrating the skin of barbers' hands, and all eye departments see as patients hairdressers and barbers who complain of hairs penetrating the conjunctiva Although "cysts" are produced in the skin, these do not grow hair The accompanying figure shows a typical example of multiple sinuses in the web of a barber's hand Each contained a hair, which could readily be removed with forceps This patient has had recurring trouble over many years, and when the sinuses became infected, the cysts they formed needed opening



London W 1

CLARA M WARRES

SIR —I read Mr Jenkins's letter with interest A few hours earlier I had examined a similar case

The patient was a barber, aged 43, who complained of a tender nodule on the radial side of the middle finger, just distal to the web space, which he had noticed for 6 months Later a small sinus had developed from which hairs had been picked When I examined him there was a swelling about 1 cm in diameter with some surrounding inflammation I advised him to allow this to settle down, and to have the cyst excised later

HEALTH SERVICE ESTIMATES 1951 52

SIR,—Reading your leading article of April 7 and also p 794 (col 2), I am surprised that you said nothing about the entry which shows an expenditure of £21,144,000, in the hospitals of England alone, on salaries and wages of "other staff" Surely after taking into consideration all the main items—Medical Staff, Nursing Staff, Ward Orderlies, Works Maintenance Staff, Laundry Staff, Farm and Garden Staff, Administrative and Clerical Staff, Professional and Technical Staff, Catering Officers, Cooks, and Kitchen Staff—an item of £21,144,000 for *other* staff should not be allowed to go without comment What other staff can there be left who require nearly as much money as the entire Medical Staff, including specialists? Such slovenly accountancy seems strange to me, and I think the taxpayer is entitled to more detailed information than we are given here

Attention was drawn to this item by a special correspondent in the *British Medical Journal* of April 7, and I hope that those responsible for the estimates will now throw more light on the subject

HAROLD LEESON

Parliament

Trimming Our Coat

In the speech in which he introduced a Budget hich he declared to be honest if not popular, Mr **HUGH AITSKELL**, the Chancellor of the Exchequer, pointed out at the gross estimate for the National Health Service England, Wales, and Scotland for the year 1951–52 as nearly £470 million Receipts from the Insurance und and staff pension contributions brought this figure own to about £398 million This total was £25 million ss than the estimate originally submitted to him, which as £30 million above last year's estimate The increase as mostly due to higher prospective expenditure on he hospital services But with all the other burdens be carried the Government did not feel it reasonable pass another £35 million on to the Exchequer and herefore on to the taxpayer, so they decided that the ealth service must be kept within a total of £400 million, hich for the time being must be the ceiling The Minister of Health and the Secretary of State for Scotland would make all practicable economies in the course of heir administration, but it was plain that the only way to keep within this limit, without reducing the tandard of the hospital, family doctor, and consultant ervices below what was really essential, was to find some ther source of revenue The Government had therefore decided, Mr Gaitskell said, to introduce a modest charge or dentures and spectacles In the dental service all extractions and conservation would still be free, but a charge of about half the scale fee would be made in future or all denture work Expectant and nursing mothers would continue to receive free dental treatment, including dentures, from the local-authority services, and children would receive free treatment in schools as now A charge of about half the cost of each pair of glasses would also be made, but there would be no charge for children's spectacles People for whom these charges would be a hardship would be reimbursed, in whole or part, from the National Assistance Board in the ordinary way Legislation would be introduced shortly, and the details of the proposals would then be further explained Mr Gaitskell expected the new charges to yield about £13 million in 1951–52 and about £25 million in a full year The intention to make all practicable economies and to impose these charges had already been allowed for in the estimates lately presented to the House [1]

The Government, Mr Gaitskell admitted, made these changes with regret, but he believed that most people would agree that while it was reasonable to allow a slight increase in expenditure on health—some £7 million above last year—it was also necessary, against the background of our general financial position and remembering the proposed increases in the old-age pensions and on the hospital services, to impose a limit and accept that some charges should be made in the National Health Service The Government thought that they had struck a fair balance between one item of social service and another The charges would not normally fall on those who were seriously ill, such as hospital patients They applied where there was least danger of hardship and perhaps more danger of abuse than anywhere else in the health service

The Debate

In the course of the debate on the Budget Mr **JOHN BAIRD** objected to the new charges because they were completely unnecessary and because they involved a major principle People argued that there had been considerable abuses in the health service and that by making a charge for dentures and spectacles we should stop these abuses In his view these abuses, so far as the dental side was concerned, had come, not from the patients, but from the dentists He did not say that every dentist was involved, but a small section of dentists had abused the Act and nothing had been done to stop them. Most of the patients had needed treatment and many of them could not afford to pay for it He therefore hoped that the proposal would be withdrawn During the last year the dental estimates had fallen by something like £10 million, and since the beginning of this year the demand for dentures had fallen, he believed, by about 20% The great demand was now satisfied For instance, last year it was impossible to find a dental mechanic, today in the London area there were 120 looking for work.

He also believed it was wrong in principle to have a ceiling for the health service Why was it necessary, he asked, to have ceilings for great social measures like the food subsidies and the health service where there was none for other forms of expenditure? Was there no waste in the Service departments? If the cost of living continued to go up the cost of the health services would go up An ageing population would increase the hospital population and throw further cost on the health service He believed that doctors were asking for more pay, and compared with other branches of the service they could make out a good case But if the cost of the service continued to go up and the ceiling remained at £400 million, what would the next charge be? Already it had been suggested that we should have a charge for visits to the doctor Perhaps there would soon be a charge for beds in hospitals Let no one imagine this would stop at a charge for false teeth The Government should think again before they jeopardised our free health service for the sake of a mere £13 million.

Mr **RICHARD EWART** agreed that the National Health Service had contributed to the rise in the standard of living of all the people in this country But if there were to be savings he believed the Chancellor had applied those savings in the right direction, where the necessity was non recurrent for several years and might reasonably be expected to be borne An attack on the health service—a charge on consultants' fees, as envisaged by the Opposition, and on medical or hospital services—would mean a reduction in the standard of living of the whole community The Chancellor had taken the right steps to resist this

Mr **RALPH ASSHETON** congratulated the Chancellor on his courage in making these charges for the health services A free service had meant that many who most need the health service found themselves pushed aside We all wanted to get the best we could out of the service, but he was not sure that the present system of centralised control over the hospitals was effective, and he thought we should have an independent inquiry The strongest indictment of the health service, he pointed out, came from an unexpected quarter—the Socialist Medical Association's pamphlet *The L S.D of the National Health Service* Had the general practitioner, Mr Assheton asked, any incentive to prescribe economically? Had the patient any incentive to use the service economically?

QUESTION TIME

Tuberculosis Treatment in Switzerland

Replying to a question Mr **HECTOR MCNEIL** Secretary of State for Scotland, said that Parliament would shortly be invited to consider legislation enabling arrangements to be made under the National Health Service for giving treatment outside Great Britain to people with respiratory tuberculosis For this year from 150 to 200 beds in Swiss sanatoria would be made available for patients from Scotland, with the necessary transport facilities To minimise the travelling involved the selected patients would normally be people in need of at least six months' sanatorium care but unlikely to require any major surgical operation. Treatment in Switzerland would be offered to persons recommended for sanatorium treatment in the ordinary way where on medical grounds this was considered appropriate by the responsible tuberculosis physicians

Brigadier **FRANK MEDLICOTT** asked the Minister of Health what was the present position of his discussions concerning the possibility of tuberculosis patients being treated in Switzerland under National Health Service arrangements—Mr **H. A. MARQUAND** replied Arrangements are now being worked out for the use of about 160 beds in Switzerland for suitable patients from England and Wales suffering from respiratory tuberculosis, and it is hoped to start sending patients out in a few months time

Hospital Registrars

Mr **HUGH LINSTEAD** asked the Minister of Health whether he would now make a further statement to reassure those registrars whose services were threatened with termination in accordance with circular R H B (50)106 —Mr MARQUAND replied I should prefer to await the outcome of discussions now proceeding

---

[1] See *Lancet* March 31 1951 p 750

Hospital Accommodation for the Chronic Sick in London

Commander A H P NOBLE asked the Minister whether he would give an estimate of the number of chronic sick in London awaiting admission to hospital —Mr MARQUAND replied On Dec 31, 1950, there were 1324 patients on the waiting lists for admission to chronic sick beds in National Health Service hospitals in the county of London

Agenisation of Flour

Mr G C TOUCHE asked the Minister of Food whether his attention had been called to statements made at an inquest at Hull recently regarding the effects of the agenisation of flour, and whether he would make a statement on the subject —Mr F T WILLEY replied I am aware that certain allegations were made which were controverted by expert evidence at the inquest Recently a scientific committee reviewed the subject of flour improvers but was unable to find any evidence that agenised flour is in any way toxic to man

In answer to written questions Mr WILLEY stated that agreement had been reached with the milling industry to stop the use of 'Agene' and the choice of an alternative improver was under consideration Probably about 90% of flour used for human consumption was at present agenised

Doctors and National Insurance

Sir WALDRON SMITHERS asked the Minister of National Insurance if a doctor who worked for the National Health Service was, for the purposes of National Insurance contributions, classed as self employed or employed by the State —Mr H B TAYLOR replied The conditions under which doctors work for the N H S vary, but a general practitioner on the list of an executive council will normally be regarded as self employed for the purposes of the National Insurance Act

Public Health

Bathing in the Thames

WHEN the warmer weather comes many thousands of people will again be bathing in the Thames, and the question arises whether the risk to their health is becoming excessive

The Thames has always received sewage, but formerly the bacterial pollution was relatively slight because the sewage was diluted by a vast volume of flowing water and because river water has some power of self-purification In recent years, however, riverside populations have grown and the amount of sewage discharged into the river has increased in proportion As a result bacterial pollution may be approaching a dangerous level

Two years ago the Windsor baths were closed because of river pollution, but, when the question was raised, the Thames Conservators[1] and the Minister of Health[2] gave assurances that the river was no less safe than it had ever been This year the Eton College authorities, following the example of Windsor borough council, have stopped river bathing, and on April 6 in a letter to the *Times* Mr Cosmo Russell[3] called for an investigation by a "strong departmental committee" to discover ways to remedy the present state of affairs His letter was the subject of a report to the Thames Conservancy Board by its chairman, Sir Jocelyn Bray[4] On this occasion the board did not deny that pollution of the river had increased, but the chairman said that it did not fear the appointment of a committee, as suggested by Mr Russell, for he did not see what a committee could discover that was not already well known No river, said Sir Jocelyn, could possibly be of the standard laid down for swimming-baths by the Ministry of Health Even the "near safe" conditions of a properly constructed swimming-bath could not be produced in a river like the Thames which received large volumes of surface water and effluents Even if all effluents were 100% chemically pure, the river would not be bacteriologically safe, and it was the bacterial pollution which was the cause of apprehension by the Eton College authorities and others In reply to a question the chairman said that there was no definite instance of poliomyelitis or any other disease having been contracted through bathing in the Thames He added that neither in the Hobday report nor in the River (Prevention of Pollution) Bill now before Parliament was any mention made of steps to deal with bacterial pollution Obviously, he said, this was because it was practically impossible to do anything

There seems to be no doubt that pollution of the Thames has increased It is true that there is no proof of disease having been contracted as a result, but, as Albury has said in our columns,[5] it is equally true that there is no disproof While it is generally agreed that the dangers of contracting disease in a properly equipped swimming-bath have been exaggerated[6] it is probable that river water with a high bacterial content is dangerous to bathers Unfortunately, ordinary methods of sewage disposal have little effect on the bacterial content and elaborate methods of sterilisation would be necessary to render it bacteriologically pure. Much was expected from the Act of 1948[7] but it is obvious that as far as the Thames is concerned the position is becoming one of urgency

Obituary

KENNETH DOUGLAS WILKINSON

O B E, M D Birm, F R C P

Dr K D Wilkinson, physician to the Birmingham United Hospital and consulting physician to the Children's Hospital, who died at his home in Edgbaston on April 12, had held the chair of therapeutics in the University of Birmingham from 1925 to 1946

He was born in 1886 at High Legh, Cheshire, the son of the Rev H C Wilkinson, and he was educated at Berkhamsted School and the University of Birmingham. As a student he already showed both his practical ability and his aptitude for writing, and in 1908 he was awarded the Richardson essay prize, and, when he graduated M B the following year, the senior prize in clinical medicine During the next two years he held house appointments at the Queen's Hospital and at the General Hospital, Birmingham, before he became R M O at the General Hospital In 1912 he took his M D, and the following year he spent some months in London at the Hospital for Sick Children, Great Ormond Street, as a casualty officer On his return to Birmingham he was appointed to the staff of the Children's Hospital, and the following year he also became assistant physician to the General Hospital

[Elliott & Fry

He was thus well embarked on his career when war broke out in 1914 During his service with the R A M C he developed the interest in cardiology, already shown by his early papers on heart block, in his work with G E Gask on wounds of the chest Dr Wilkinson was appointed O B E for these services and mentioned in despatches

On demobilisation he returned to Birmingham to take up again his work as a consultant and teacher In 1920 he was elected F R C P, and the same year he was appointed to his chair As a lecturer he was lucid and incisive He knew how to point his clinical teaching with telling anecdotes, but his students found themselves remembering the principles he described as well as his amusing illustrations He examined for the universities of

Cambridge and Manchester and for the Royal College of Physicians. His continuing interest in cardiology led him to study the problems of rheumatism especially in children, and he chose as the subject of his Ingleby lectures in 1935 Rheumatism and its Results. In 1949 he also gave the St. Cyres lecture in this specialty.

In 1925 his *History of the Birmingham Medical School* appeared, and last year he was joint author of *William Withering of Birmingham*. His profound knowledge of 18th century Birmingham enabled him to set Withering against a vivid and varied background. Of Wilkinson the man, a colleague writes: "He really enjoyed life—his work, his recreations of golf, sailing, and bridge, his family life, and his friendships. Full of anecdotes, an authority on dialect, and a great mimic, he was an entertaining companion. Many of his younger colleagues will remember his generosity."

Dr. Wilkinson was twice married. His first wife, formerly Miss Phebe Homewood, was a sister at the Queen's Hospital, and he leaves three sons and a daughter by this marriage. His second wife, Dr. Agnes Crozier, survives him with a son and two daughters.

ARTHUR SYDNEY BLUNDELL BANKART

M.A., M.Chir. Camb., F.R.C.S.

Mr. Blundell Bankart, who died on April 8, was one of the fathers of British orthopædic surgery, and his influence was felt throughout the world.

Arthur Sydney Blundell Bankart was born in 1879 the son of James Bankart, F.R.C.S., of Exeter. He was educated at Rugby, at Trinity College, Cambridge, and at Guy's Hospital. After qualifying in 1906 he held a resident post at Guy's for a year before he decided to take up surgery. The academic hurdles presented no obstacle, and he became a fellow of the Royal College of Surgeons of England in 1909 and a master of surgery of the University of Cambridge the following year. During this period he came under the influence of two great men, Arbuthnot Lane and Charles Sherrington. From the former he learned the no touch technique that made bone surgery comparatively safe at a time when the aseptic ritual was still at a primitive level, and which he was able later to pass on to others of the now growing band of orthopædic surgeons. But—and perhaps this was more important—he acquired from Sherrington the experimental approach to disease, an attitude of mind that he retained throughout his life.

By courtesy of the Journal of Bone and Joint Surgery

Bankart was attracted from the first by the possibilities that were opening at the borders of the surgical field. His inquiring mind was very ready to turn from the old to the new, and it was natural that he should enter one of the embryo specialties. In 1909 he became the first surgical registrar at the newly formed Royal National Orthopædic Hospital. Dexterous of hand, preferring the operative side of surgery, and well primed with the new Lane technique, he took full advantage of the opportunity. The surgeons of those days took a leisurely two months' holiday each summer, leaving their hospitals deserted and their patients awaiting their return. Bankart loved to tell how, as soon as he was left alone, he emptied all the beds and filled them with new patients whom he could treat without restraint. In 1911 he was appointed assistant surgeon to the Royal National Orthopædic Hospital, and in the same year he became assistant surgeon to the Queen's Hospital for Children and the Belgrave Hospital, and surgeon to the Maida Vale Hospital for Nervous Diseases. This was in the days before the surgical specialties had become a closed shop, and he was practising orthopædics, general surgery, and neurosurgery. This last attracted him greatly and he continued with it almost until the late war. Indeed, stimulated by Campbell Thompson, he carried out much of the neurosurgery at the Middlesex Hospital. Orthopædics, however, was always his first love and it was in this field that he made his chief contributions.

The outbreak of the first world war thus found him already on the honorary staff of four hospitals, and to this burden he added a number of the smaller military hospitals in the London area. Then, shortly after Shepherd's Bush was opened, Bankart joined Robert Jones's team there and this became the busiest time of his energetic career. After the war he was elected to the staff of the Middlesex Hospital as its first orthopædic surgeon. He gave up his appointments at some of the smaller hospitals to be free to devote more of his time to the uphill task of developing a new department in an old-established institution.

His position in the orthopædic world was quickly recognised. In 1913, he became the first honorary secretary of the newly formed subsection of orthopædic surgery of the Royal Society of Medicine, and in 1925 he was elected president of the section. A founder member of the British Orthopædic Association, he was honorary secretary of the association from 1926 to 1931 and president in 1932 and 1933.

P. W. writes: "Bankart is perhaps best known for his operation for recurrent dislocation of the shoulder, a procedure now used by nearly every orthopædic surgeon in the world and out of the hundred or more described for the relief of this condition the only really reliable one. His influence on orthopædics in nearly every field was profound because he had a directness of approach that excluded careless thought and slipshod work, and he was quick to debunk an unsound or superficial argument. His attitude to manipulative work is an example. He saw the good results so often obtained by bonesetters and manipulators and took the trouble to find out what they actually did. He got to know Herbert Barker, watched him work, and followed up his patients. He reduced the claims from 'miracles' to plain facts, showed when manipulation was indicated, made it a 'respectable' procedure, and put it on the orthopædic map, and the culmination of this work was his book, *Manipulative Surgery*, published in 1932.

"He was a shy man and for this reason few of his colleagues knew him well, but those who did loved him greatly. I owe him more than I can say. He took me as a young man, taught me his craft, and made my way easy. He was always helping others, but he did it so unobtrusively that often they would be unaware of what he had done. A connoisseur of the good things of life, he had little use for mediocrity. He liked fine furniture, fine wine, and fine men."

Mr. Bankart married Beryl Winifred, daughter of Mr. A. S. Moss-Blundell, who survives him with one daughter.

ROBERT BROOM

M.D., D.Sc., LL.D. Glasg., F.R.S.

Dr. Robert Broom died on April 6 at the age of 84. His name will for ever be associated with two most important themes in palæontology—the mammal-like reptiles which have provided so much information on the problem of the origin of mammals, and the fossil ape-like creatures of South Africa, the Australopithecinæ, which have contributed such abundant evidence bearing on the origin of man. All these achievements were the product of an amazing energy, mental as well as physical.

Born in 1866, at Paisley, the son of John Broom, a shawl designer and art connoisseur, he studied at Glasgow University where he graduated in science in 1887 and in medicine two years later. During his medical course he came under the influence of John Cleland, professor of anatomy, who was one of the main sources of inspiration for his pursuit of evolutionary studies in later years. He became particularly interested in the question whether mammals had their evolutionary origin from reptilian or amphibian ancestors—a problem which at that time was a matter of active dispute among comparative anatomists. This was one of the reasons why he went to Australia in 1892, for he thought the land of the monotremes might provide important evidence for comparative anatomical studies. During the next few years he published a number of papers dealing with the anatomy of monotremes and marsupials. While in Australia his attention was drawn to the importance of fossil evidence in the elucidation of evolutionary problems His stimulating contact with a remarkable group of biologists who at that time were working together at the University of Sydney—Elliot Smith, J P Hill, Haswell and J T Wilson—led to further contacts by correspondence with biologists in other parts of the world, and it was partly due to the influence of the American palæontologist Osborn that he went to South Africa in 1897 to search for fossil evidence of the evolutionary transition from reptile to mammal The years of productive work which followed were marked by a series of important papers on fossil mammal-like reptiles, many of them reporting the discovery of new types, and on problems of comparative anatomy and vertebrate evolution In 1913 Broom was invited to deliver the Croonian lecture before the Royal Society, in 1920 he was elected to the society, and in 1928 he was awarded one of its Royal medals

To carry out his explorations, Broom engaged in medical practice in out-of-the-way places with the immediate intention of seeking for fossils in the locality Not that he neglected his patients (who in these remote districts were often very few), for according to all accounts he was regarded with great affection by them But he had to live a life of great austerity, not to say poverty, in order to satisfy his scientific interests As a result of his work during these earlier years, he became one of the leading authorities on the mammal-like reptiles Later, Dart's discovery of Australopithecus inspired him to search for more remains of this extinct ape-like form He was convinced that Dart was right in his conclusion that, in spite of the simian proportions of the brain and jaws, Australopithecus showed morphological characters in the skull and dentition which approximated to the Hominidæ rather than to the anthropoid apes With remarkable insight and energy Broom sought, and found, abundant remains of the Australopithecinæ in stalagmitic deposits near Pretoria, and at the time of his death he had discovered, and described, many skulls, jaws, teeth, and limb bones of adults, juveniles, and infants

"Each new discovery," writes W E Le G C, "brought new confirmation of the astonishing mixture of hominid characters with primitive ape like characters in the Australopithecinæ It is not surprising that these discoveries gave rise to acute controversies, indeed, this may be taken as a measure of their importance, for sharp controversies have always accompanied equally important discoveries in the past (It was, for instance, vigorously contended at one time that Pithecanthropus was nothing more than a giant gibbon, or that Neanderthal Man was nothing more than a pathological monstrosity) It is fair to say, however, that almost every authority now recognises the existence in the Australopithecinæ of hominid characters which are not to be found in the anthropoid apes, even though there may be still some difference of opinion as to their precise significance

"Broom used to maintain that the paucity of fossil evidence bearing on human evolution was mainly due to the fact that palæontologists did not look in the right places and did not pursue their searches with enough vigour He himself certainly had a remarkable flair for going to the right places to hunt for fossils But more than that, he possessed a drive and energy which overcame all obstacles and brooked no opposition in his eagerness to find what he was looking for Practically up to the time of his death, he was still working with amazing energy Few men who die at the age of 84 have achieved more in the acquisition of new scientific knowledge than he In his passing we can but feel a deep sense of gratitude for his single-minded devotion in his field of work, and pay our respects to a man who was so outstanding as a discoverer To those of us who knew him personally, his generosity and kindness will be remembered as among the most prominent of his qualities If he permitted his dry Scotch humour to let itself go sometimes in outspoken criticisms of those who threw doubt on the validity of his conclusions—particularly those who did so without having even seen the original fossil specimens—his criticisms were always made with a characteristic twinkle in his eye"

Notes and News

KING EDWARD VII's HOSPITAL FOR OFFICERS

At the request of King Edward's Hospital Fund a consulting staff has been appointed to King Edward VII's Hospital for Officers, Sister Agnes Foundation, Beaumont Street, London, W 1 The council of the hospital are anxious, however, that the specialists and practitioners not on the staff should continue to use the hospital, and the council have laid down that patients may be admitted under any doctor of their own choice The hospital is now for serving, retired, and ex temporary officers of the Forces, and the fees are from 7 to 15 guineas a week according to the nature of the accommodation and subscription rights of patients

CONTROL OF ANTI-HISTAMINES

In this country there have been several fatalities among children who have swallowed tablets containing anti-histamine drugs[1], and last year this group of drugs was added to part 1 of the Poisons List and the first schedule. In the U S.A these compounds are still widely taken as a remedy for the common cold, despite substantial evidence that they have little or no value against this ill[2], and the committee on public health relations of the New York Academy of Medicine states that 8 infants under two years of age are reported to have died from accidental consumption of the tablets, while several others are reported to have had convulsions "Packages of antihistaminic drugs sold to the public," says the committee, "carry directions for dosage, but this is not sufficient protection against accidental over dosage or other hazardous use, especially in children. Allergists have estimated that at least 20 per cent of the people who take anti histamines in the doses recommended will experience undesirable if not dangerous reactions. Several persons are reported to have attempted suicide by taking excessive doses of antihistaminic drugs, and one succeeded"

THE CIBA FOUNDATION

The Ciba Foundation for the Promotion of International Coöperation in Medical and Chemical Research was founded by Messrs Ciba in September, 1947, to encourage study and research in all branches of medicine and its allied sciences. The foundation building was opened in London at 41, Portland Place, W 1, on June 22, 1949, the founders felt that the English language had become the scientific language of the world and that London was the ideal world centre The foundation serves as a meeting place for research workers from all over the world, provides accommodation for foreign visitors, and bestows grants to enable scientists from one country to work in another To begin with it was decided to confine its activities mainly to the international exchange of ideas on the steroid hormones, and a specialist library is being built up on this basis

The first report covers the period June, 1949, to December, 1950 During this time 1800 people, including visitors from 17 countries, have attended meetings at the foundation or have visited research institutions under arrangements made by the foundation It has worked in close coöperation with the medical societies, the University of London, the British Council, the Ministry of Health, and the scientific section of the French Embassy Many of the societies have held meetings at the centre, and one, the Hunterian Society, has held an exhibition at the foundation

The Ciba Foundation lecture for 1949 was given by Prof E C Dodds, F R S, and the lecture for 1950 by Sir Stanton Hicks, University of Adelaide Eight conferences were held, six concerned with the steroid hormones and two with general subjects The proceedings of one of the general meetings have been published in book form, and it is hoped to publish an account of the other meetings shortly The resources of the library have been strengthened by an arrangement whereby guests are allowed to use the library of the Royal Society of Medicine

The trustees of the foundation are Lord Beveridge, Lord Horder, Prof E D Adrian, O M, F R.S, and Mr Raymond Needham An executive council has been set up and is helped by an advisory board consisting of 13 members from Great

OUR KNOWLEDGE OF THE MENSTRUAL CYCLE, 1910-1950*

GEORGE W CORNER
M.D , Sc D
DIRECTOR, DEPARTMENT OF EMBRYOLOGY, CARNEGIE INSTITUTION OF WASHINGTON, BALTIMORE

THE founders of the Addison lectureship, Dr Harry Spon and Dr Peter Bishop, challenged the successive speakers not only to convey information upon the topics of their choice, but also to trace the development of the ideas of modern endocrinology, and above all to present a picture of the medical investigator in action, with all the fascination of his problems and his hopes of useful discovery

I am going to try therefore to tell you the story of the development of our knowledge of the menstrual cycle as it has been worked out during the past four decades This is the subject which has chiefly occupied my own energies during that period, and the story will necessarily have a large element of personal reminiscence

INTRODUCTION TO GYNÆCOLOGY

When I entered the Johns Hopkins Medical School in 1909 after a good training in zoology, I was presented almost at once with an opportunity to try my hand at an embryological investigation This involved collecting pig embryos at a nearby abattoir Thus I learned to know the reproductive tract of the pig and something of its embryology at first hand, from the fresh specimens

This work stimulated my interest in gynæcology, and I determined to seek an internship in that specialty I was on the point of obtaining one when Franklin Mall, the professor of anatomy, offered me an assistantship, with the surprising argument that this would be the best pathway to usefulness in the women's clinic He pointed out to me prophetically that the gynæcologists, then basing their superb diagnostic skill and surgical art upon pathology, would soon find themselves involved in physiological problems for which no sound basis of biological knowledge existed Ten years in his laboratory, he said, working at embryology and the physiology of reproduction, would be the best preparation for the new gynæcology

During the one year in which I actually worked with him, Mall set me at the task of describing the sow's corpus luteum during its earliest phases He thought it would be possible to date very early human embryos by histological study of the corresponding corpora lutea This task, incidentally, was not accomplished until many years later, and then in the reverse direction, for our present ability to date the early corpus luteum in primates by microscopical examination was gained largely by studying embryos of known age

At the end of my anatomical year I went into the gynæcology department, and there, although my chief, Howard A Kelly, was one of the best pathologists and surgeons of our country, I saw what Mall meant when he said that gynæcologists did not understand the human cycle Looking back from our present standpoint, one can see that the dawn of the modern physiology of reproduction had begun, but few of its rays were as yet reaching into the gynæcological operating room

THE REPRODUCTIVE CYCLE

That the ovaries are fundamentally necessary to the occurrence of menstruation was first explicitly conjectured by a young Marylander, John B Davidge, in 1793, but this fact did not become a matter of general medical knowledge until the 1860s Meanwhile K E von Baer's discovery of the mammalian ovum in 1847 led to a general exploration of the reproductive cycles of lower (non-menstruating) mammals It became known through the studies of Bischoff, Pouchet, and many others that in domestic animals the ovarian follicles mature and shed their eggs at the time of œstrus, and that the corpora lutea formed after ovulation are contemporaneous with the developing embryos At the end of the 19th century this framework was being filled in with a great mass of detailed information about animal cycles Two English writers had an important part in systematising and summarising this knowledge—Walter Heape of Cambridge, who defined and named the various stages of the œstrous cycle, and another Cambridge don, F H A Marshall, who gave us after the turn of the century an enlightening book, *The Physiology of Reproduction*, which served to introduce many readers to this growing field of study

Marshall's analysis of the dog's and rabbit's cycles, Leo Loeb's studies on the guineapig, J P Hill's on the marsupials, and various other descriptive researches, were beginning to teach us the general picture of the mammalian cycle, characterised by recurrent periods of œstrus, when the follicles shed their ova and are converted into corpora lutea Gustav Born's hypothesis that the corpus luteum has the function of preparing the uterus for the implantation of the embryo, communicated personally to his student, Ludwig Fraenkel, was announced by the latter and demonstrated by experiments on rabbits published in 1903 and 1910 This discovery at last made the cycle understandable in terms of reproductive function.

It had been realised, of course, immediately after von Baer's discovery, that the human menstrual cycle is in some way related to the cycle of ripening and shedding of the egg cell. The precise relation of the human menstrual cycle to the œstrous cycle of non-menstruating animals was, however, still obscure except to a few pioneer investigators at the time I am now discussing—i.e , the second decade of the present century

TWO ERRONEOUS NOTIONS

It was thought by many that the menstrual flow is comparable to the œstrous phase of the animal cycle This fallacy was based upon the assumption that as œstrus is the most conspicuous event of the cycle in lower mammals, and menstruation is the major event in the human species, they must be the same, and also upon a supposed analogy between menstruation and the pro œstrous bleeding that occurs in the cow and the bitch. On the other hand, many pathologists and gynæcologists who had examined human ovaries had failed to find evidence of ovulation at or near the time of menstruation They taught that there is no direct relation between the menstrual cycle and the time of rupture of the successive graafian follicles

These two erroneous notions had to be abandoned as a result of investigations published in the first decade and a half of the 20th century Hitschman and Adler of Vienna showed in 1908 that certain remarkable changes in the glands and stroma of the endometrium which had been classified as "glandular endometritis," and were attributed to inflammatory disease, actually represent a phase of the normal cycle characteristic of the premenstrual stage Three years later Ancel and Bouin proved by brilliant experiments on rabbits that similar changes seen in that species are produced by action of the corpus luteum With these clues, two German gynæcologists who had access to great stores of human material, Schroeder and Robert Meyer, soon worked out the general pattern of the human cycle On the basis of all these investigations, it was established that

* Fourth annual Addison lecture, delivered at Guy s Hospital, London, on July 13, 1950

Fellowship of Postgraduate Medicine

The offices of the fellowship and of the *Postgraduate Medical Journal* have been moved Their new address is 60, Portland Place, London, W 1 The telephone number is unchanged (Langham 4260)

Film on Tropical Sprue

The Wellcome Film Unit has produced a film in 16 mm colour, silent (running time 6½ minutes), on tropical sprue It is primarily intended for showing to medical undergraduates, and applications to borrow it (case record no 5) should be sent to the unit, 183–193, Euston Road, London, N W 1

Films on Parasitology

A provisional list of films dealing with human and comparative parasitology has been compiled on behalf of the International Scientific Film Association by Dr Willem de Vogel, c/o Universitaire Film, Catharijnesingel 59, Utrecht, Holland He would be glad to have any additions or corrections, so that a permanent catalogue, with periodical supplements, may be set up

Renal Association

A meeting of this society is to be held at the Ciba Foundation, 41, Portland Place, London, W 1, on Thursday, April 26, at 4 30 P M Prof K J Franklin will speak on the Kidney and the Circulatory System, Dr A H Galley on Spinal Anæsthesia and the Kidney, and Dr Telford Govan on Renal Changes in Obstetric Shock On Wednesday, April 25, at 4 30 P M at the Wellcome Institution a film will be shown on the Kidney in Health and Disease

Diary of the Week

APRIL 22 TO 28

Monday, 23rd

Royal Eye Hospital St George's Circus Southwark S E 1
5 P M Prof Arnold Sorsby Detachment of the Retina
Institute of Ophthalmology Judd Street W C 1
5 30 P M Mr A B Nutt Congenital Ocular Palsies
Medical Society of London, 11 Chandos Street, W 1
8 30 P M Dr J H Burn, F R S Dr Richard Doll Effects of Tobacco Smoking

Tuesday, 24th

Royal Eye Hospital
5 P M Dr T H Whittington Astigmatism Factors Affecting Binocular Vision Convergence
Westminster Medical School Horseferry Road, S W 1
5 P M (Meyerstein lecture theatre) Clinicopathological meeting on Influenza

Wednesday, 25th

Royal Eye Hospital
5 P M Mr R P Crick Buphthalmos
Institute of Ophthalmology
5 30 P M Dr L C Thomson Electrophysiology of the Retina
Royal Institute of Public Health and Hygiene 28, Portland Place W 1
3 30 P.M Dr Henry Yellowlees Hypnotism—Its Uses and Limitations in Medicine
University of Glasgow
8 P M (Department of Ophthalmology) Prof W J B Riddell Emotions and Eye Disease

Thursday, 26th

Royal College of Surgeons Lincoln's Inn Fields, W C 2
3 45 P M Dr L Foulds Experimental Study of the Course and Regulation of Neoplasia (Imperial Cancer Research Fund lecture)
Royal Army Medical College Millbank S W 1
5 P M Major R A Smart Biting Insects in the North
Royal Eye Hospital
5 30 P M Miss J M Dollar Ocular Therapeutics
University College Gower Street W C 1
4 45 P M Prof H A Krebs F R.S Energy Transformations in Living Matter (First of four lectures)
Medico Legal Society 26, Portland Place W 1
8 15 P.M Dr R Donald Teare Medicolegal Significance of Death following Abortion
Honyman Gillespie Lecture
5 P M (Anatomy Theatre University New Buildings Teviot Place, Edinburgh) Dr R H Girdwood Vitamin B_{12} and Folic Acid in the Megaloblastic Anæmias
University of St Andrews
5 P M. (Medical School Small's Wynd, Dundee) Prof W C Wilson Circulatory Changes in Surgical Conditions

Friday, 27th

Royal Eye Hospital
4 30 P M Mr A J Cameron Surgery of Cataract
Institute of Ophthalmology
5 30 P M Prof D Slome Sensitivity of Ocular Structures
Medical Society for the Study of Venereal Disease 11 Chandos Street W 1
8 P M Dr W D Nicol with Dr M Whelen Use of Penicillin in the Treatment of Neurosyphilis

Appointments

Births, Marriages, and Deaths

BIRTHS

Baird—On April 10, at Guildford Surrey the wife of Dr J T Baird—a son
Freeman—On April 12 in Cardiff the wife of Dr A G Freeman—a son
Greig—On April 9 at Stornoway Lewis the wife of Dr J C R. Greig—a daughter
Henderson—On April 9 at Harpenden, Herts, the wife of Mr R S Henderson F R C S—a son
Lloyd—On April 8 the wife of Dr J T A Lloyd—a son
Lucas—On March 29 at Stratford on Avon, the wife of Dr D R. Lucas—a son
Macdonald—On April 12 at Taplow Bucks, the wife of Dr Angus Macdonald—a daughter
Pyke—On April 13 in London, the wife of Dr David Pyke—a son
Smerdon—On April 12, in Liverpool the wife of Dr Geoffrey Smerdon—a daughter
Till.—On April 11 at Oxford the wife of Mr A S Till, F R C.S.—a daughter

DEATHS

Anderson—On April 13 at Bungay Frank Ernest Anderson, M B St. And
Bankart—On April 8 Arthur Sydney Blundell Bankart, M A, M CHIR. Camb F R C S
Comyn—On April 14, at Hythe Kent, Arthur Fitzwilliam Comyn B.A M B Camb, aged 68
Elliott—On April 13 at Wolverhampton, Kenneth Alwyne Elliott, M.R.C.S aged 29
French—On April 13, John Gay French, M.S Lond F R.C.S, aged 79
Games—On April 11 at Eccles Lancs, John Henry Paisley Games, M R.C S aged 62

Stacpoole—On April 12 at Shanklin I o W Henry de Vere Stacpoole L.S A aged 88
Whitehead—On April 9 at Stockport, Cheshire Alfred Whitehead L.R C P E, aged 78
Wilkinson—On April 12, in Birmingham Kenneth Douglas Wilkinson O B E M D Birm, F R C P

Sir George McRobert, F.R C P, is visiting *Portugal*, under the auspices of the British Council He will lecture at the Institute of Tropical Medicine and at the British Institute in Lisbon, and at the faculty of medicine in the University of Oporto

A booklet on *Appointments in His Majesty's Colonial Service* is obtainable from H.M Stationery Office (pp 125 2s) support by the ovarian hormones No other tissue in the body, so far as we know, ordinarily reacts in any such way to hormone deprivation, nor does the endometrium itself react thus in other mammals Speculation upon the question was more or less sterile until special attention was directed to the endometrial blood-vessels Bartelmez in 1929 declared that his study of the menstruating human uterus revealed no constant factor in menstruation except vascular changes involving rhexis

---

* Amended notice

Much light was thrown on the question by the appearance in 1940 of Markee's remarkable experiments upon rhesus monkeys, in which he transplanted bits of endometrium to the anterior chamber of the eye, where they attached themselves and became vascularised Such implants bleed into the aqueous humour at the time of menstruation, and they respond to hormone stimulation and hormone deprivation exactly as does the endometrium at its normal site Markee was able to watch the process through the cornea, with the microscope His descriptions clearly reveal that the interruption of blood flow through the arteries supplying the endometrium is a basic factor in the menstrual process

In those species of primates which menstruate, these arteries are peculiar in that they are profusely coiled, forming striking spiral bundles as they course toward the free surface of the endometrium Various hypothetical explanations of the menstrual process, some of them crude and others subtle, have been based in recent years upon the coiled arteries, but it has become reasonably certain that the coiling is not itself involved in the periodic constriction of these vessels and the resulting ischæmia of the endometrium that leads to the menstrual breakdown There is no need to go over in this lecture the various hypotheses, some of which postulate a physiological sensitivity of the arteries, or of the vascular system in the endometrium in general, others call for the participation of arteriovenous anastomoses, which it is claimed are specially numerous in the human endometrium, or rest upon peculiarities of the lymphatic drainage of the uterus I have discussed them in the second edition (1947) of my book, *The Hormones in Human Reproduction* None of them has received convincing experimental support

I have myself vainly devoted much time and effort to experiments designed to test a conjecture that menstrual bleeding depends on the action of a hypothetical vasomotor substance to which the endometrial blood-vessels are especially sensitive, and against which they are protected by the ovarian hormones Vasoconstriction and resultant menstrual bleeding would therefore follow a sudden drop in hormone level Such a vasomotor substance might be formed in the endometrium, perhaps as a result of cell damage following hormone deprivation (e g, histamine), or it might be something normally present in the circulating blood (e g, adrenaline) The experiments (admittedly crude in concept and execution) involved direct application of the vasomotor substance to the endometrium, by injection into the uterine cavity through a fine needle In this way a whole series of vasomotor substances has been tried, and as a counter check certain vasomotor substances (e g, antihistaminic drugs) have been given systemically to see if they would inhibit œstrogen-deprivation bleeding

The only substance which has given even a suggestive result is adrenaline In 5 of 8 experiments recorded in my unpublished notes in which 0 5 or 1 ml of 1 1000 adrenaline in oil was injected into the uterine cavity of a laparotomised castrate rhesus monkey under suitable œstrogen stimulation, there was frank external bleeding in one case, and microscopic blood with an occasional clot in the vaginal washings in 4 cases This bleeding was not merely the result of the needle puncture Traumatic blood, or pigment injected with the drug, show themselves in the vagina within a day The bleeding here described did not occur until the third day after the injection I have, however, not as yet had success with the counter experiment of administering anti adrenergic drugs, which might be expected to inhibit œstrogen-deprivation bleeding In view also, however, of G van Wagenen's demonstration some years ago, that lumbar section of the spinal cord is followed by menstruation-like bleeding, one is tempted to cling to the conjecture that some one of the vasomotor substances associated with the nervous system may be involved in the menstrual process

It should be added that in our laboratory the action of neostigmine as an emmenagogue, repeatedly mentioned in American clinical literature for six or eight years past has not been confirmed on monkeys

LABORATORY AND BEDSIDE

These major mysteries of the menstrual cycle must probably be left to the younger generation for solution The older workers whose achievements I have been summarising need not however relax their efforts, for they will remember that Thomas Addison was sixty years of age when he announced the great discovery which we commemorate in this series of lectures Since these older workers began their own youthful efforts, they have seen the once incomprehensible mysteries of the human reproductive cycle yield steadily to the progress of investigation, until at last the gynæcologist is able to analyse his cases of menstrual disorders, of sterility, and of recurrent abortion with a much better understanding of the underlying physiological disturbance and with far greater hope of successful treatment than he could have had forty years ago

Franklin Mall was right when he predicted that gynæcology and obstetrics could be led to new successes by physiological research based upon embryology and the histology of the reproductive cycle The young man, however, whom he persuaded to prepare himself for a gynæcological career by way of the anatomical sciences did not become a gynæcologist, after all In 1915 the women's clinics of the United States had no place open for men who wanted to give research a major claim upon their time Perhaps the chief contribution made by those of us who gave up the satisfaction of being directly helpful to suffering fellow beings in order to embark upon the venture of research, was to reopen the way for the scientific clinician who brings research upon human endocrinology and reproductive physiology to the hospital bedside and the operating room—a pathway long ago taken by Thomas Addison, and now followed with eminent success by some of his successors at Guy's and elsewhere

BIBLIOGRAPHICAL NOTE

The foregoing lecture is not a formal review but rather a sketch of the progress of discovery as seen by one observer No attempt has been made to mention all the contributors systematically The facts discovered are now mostly in the textbooks of embryology, physiology, gynæcology and obstetrics References to the major contributions will be conveniently found in the bibliographies of the following works:

Allen E (1939) Editor Sex and Internal Secretions. Baltimore
Bartelmez, G W (1933) Histological Studies of the Menstruating Mucous Membrane of the Human Uterus *Contr Embryol, Carneg Instn.* 24 141

Corner G W (1947) The Hormones in Human Reproduction Princeton
— Bartelmez G W Hartman, C G (1945) Development, Organization and Breakdown of the Corpus Luteum in the Rhesus Monkey *Contr Embryol. Carneg Instn* 31, 117
Hartman C G (1936) Time of Ovulation in Women. Baltimore
Zuckerman S (1949) The Menstrual Cycle *Lancet*, i, 1031

such bleeding, and (3) that in a castrated female monkey administration of a course of œstrogen, followed by abrupt cessation of the hormone treatment, will cause bleeding These findings were the basis of Allen's "œstrogen deprivation" theory—i e, that natural menstruation results from withdrawal of the effect of œstrogen upon the uterus

Some years later Zuckerman put the deprivation experiments on a more precise quantitative basis, and showed that it is not necessary to cut off the entire supply of œstrogen to cause menstruation like bleeding, a sudden reduction from a high level to a much lower level will have the same effect If the daily dose of injected œstrogen is reduced gradually, instead of suddenly, the endometrium reverts to the castrate condition without hæmorrhage

Some experiments of my own were aimed at testing an obvious deduction from E Allen's deprivation hypothesis In intact monkeys which are having spontaneous menstrual periods it should be possible to prevent or postpone the menstrual flow by giving œstrogen injections so timed as to counteract the hypothetical drop of œstrogen secretion supposed to precede menstruation I was, however, unable to prevent menstruation in this way, with œstrogen injections begun in the latter half of the interval. On the other hand, relatively small doses of progesterone effectively suppress menstruation for many days or even weeks The contrary fact, that removal of a corpus luteum will cause immediate menstruation, had already been learned by clinical observations on women after gynæcological operations

Zuckerman, Hisaw, and I, almost simultaneously but independently, all did the critical experiment A castrated female monkey is given a daily injection of œstrogen in oil, sufficient to build up the endometrium to the level at which sudden œstrogen deprivation would cause menstruation like bleeding The œstrogen is, however, continued, and a course of daily progesterone is added The monkey is now receiving both hormones After ten days the progesterone is discontinued, the œstrogen being continued at the same dosage or even increased The discontinuance of progesterone is always followed after 3–8 days by bleeding, in spite of the continuance of œstrogen in quantities ordinarily sufficient to prevent œstrogen deprivation bleeding We must suppose that the administration of progesterone in some way interferes with the action of œstrogen upon the endometrium An animal receiving progesterone is thus in a sense "deprived" of œstrogen The progesterone is itself able to prevent deprivation bleeding, but when it is in turn discontinued, the monkey is physiologically deprived of œstrogen and literally deprived of progesterone Hence bleeding occurs

The current hypothesis of the rôle of the ovarian hormones in the normal human cycle is based on experiments of this type, for we must suppose that œstrogen is being secreted more or less continuously by the ovaries, whereas the corpus luteum is present and active during a part of the cycle only When it breaks down, the resulting low level of effective hormones causes the menstrual flow This scheme does not of course explain anovulatory menstruation, but there is probably a clue in Hisaw's observation that a surprisingly small single dose of progesterone administered to an intact monkey is usually sufficient to cause bleeding when its effect wears off Possibly anovulatory bleeding results from a recurrent state of the pituitary ovarian system in which a small amount of progesterone or a progesterone-like hormone is secreted by ovarian cells in the absence of a corpus luteum, or by the adrenal cortex, as Zuckerman has suggested

The history of our knowledge of the reciprocal relations between the pituitary and the ovarian hormones, which underlie the cycle in general, would require another lecture, and it would be less complete than the story I have been telling of the interrelation between the ovary and the uterus, because research still lags for want of final purification of the pituitary hormones and of refined methods of assaying them in the circulating blood

This is not to say, however, that our knowledge of the ovarian hormones in relation to the cycle is complete We are, indeed, only now beginning to obtain quantitative knowledge of the blood levels of œstrogen and progesterone in the human female at various stages of the cycle and of gestation The original Allen Doisy assays of œstrogen, refined by many workers, have been supplemented by Browne and Venning's discovery of pregnandiol glycuronidate in the urine and its application as a method of estimating progesterone excretion Very recently Hooker and Forbes, of Yale University, have given us a precise method of estimating progesterone directly in blood and tissue extracts Ultimately such procedures will reveal quantitatively the ebb and flow of the ovarian hormones in the cycle and teach us to study disorders of the cycle far more precisely than has previously been possible

PURPOSE OF MENSTRUATION

Meanwhile many basic problems of the menstrual cycle remain unsolved What, to begin with, is the functional significance of the menstrual flow? This phenomenon, in its fully developed form, occurs only in certain of the primates—i e, man, the anthropoid apes, and the Old World monkeys Other mammals reproduce their kind without periodic uterine breakdown and hæmorrhage

It was suggested, before the earliest stages of embryonic development were observed in the primates, that the first phases of the menstrual hæmorrhage might serve to provide immediate nourishment for the primate embryo, which was supposed to need special pabulum more promptly than embryos of other orders. The supposition was that menstruation is the end result of a process which serves its real purpose only if the ovum is fertilised In that case the proliferative action of the œstrogen progesterone hormone sequence carries the endometrium on through the progestational (premenstrual) stage and to a point at which the tissues are ready to provide pabulum in the form of free blood, extravasated around the implanting embryo, A further degree of hæmorrhage is inhibited by the continued activity of the corpus luteum of pregnancy In the non pregnant cycle, this preparation for useful localised extravasation goes on, when the corpus luteum retrogresses, to the frank breakdown state of menstrual bleeding

The chief evidence for such a conjecture is the occurrence of localised hæmorrhage in the vicinity of the embryo about 16 days after ovulation, and the consequent appearance of erythrocytes or even of microscopic blood in the vagina at about the same time—i e, the "placental sign" of Hartman There is, however, room for doubting whether such local bleeding around the embryonic mass is to be homologised with the general necrosis and extravasation of the menstrual period Anovulatory menstruation, moreover, seems to elude any such conjectural explanation Yet this is the one hypothesis that is at all plausible in the light of present knowledge, and if it is rejected we have not the slightest notion as to what usefulness, if any, appertains to the menstrual flow

BEHAVIOUR OF PRIMATE ENDOMETRIUM

A less philosophical but more practical problem, and one which is all the more baffling because it seems momentarily awaiting solution, is why the endometrium of the higher primates should bleed when deprived of

Case 5.—A housewife, aged 21, had had winter bronchitis since childhood and mild asthmatic attacks for two years. She was six months pregnant when admitted with a staphylococcal pneumonia She developed a synpneumonic empyema, the responsible *Staph aureus* being penicillin sensitive Aspiration on seven occasions removed 77 oz. of pus. The empyema was loculated, and the last specimen of pus obtained still contained scanty organisms The patient became apyrexial in fourteen days and was discharged in six weeks A week later she coughed up a small residual empyema and was readmitted. The pleural pus still grew a *Staph aureus* Penicillin was injected into the pleural space on one occasion only Pregnancy proceeded normally

Follow up—A year and a half later radiological evidence of tuberculosis appeared in the other lung Two and a quarter years later the patient had a very occasional cough Physical examination was normal, and the affected lung was normal on radiography The tuberculous lesion was quiescent Bronchography was not done

Case 6—A labourer aged 68 was admitted six days after the onset of an extensive pneumococcal pneumonia He developed toxic delirium extensive purpura, and a pleural effusion. This was aspirated on seven occasions and 36 oz. was removed, the fluid eventually becoming thick pus Pneumococci disappeared from the fluid after the first aspiration. The patient was discharged from hospital in seven weeks, and has not been traced for follow up

Case 7—A labourer, aged 60, was admitted on the seventh day of his pneumonia with a synpneumonic empyema. The thin stinking pus grew an anaerobic streptococcus Twelve aspirations removed 84 oz. of pus Culture became sterile in four days and smears negative in twenty six days. The patient became apyrexial in ten days, was discharged in seven weeks and returned to work eleven weeks after admission.

Follow up—Two years later he was rather emphysematous and had mild winter bronchitis Chest movement and circumference were equal on both sides The costophrenic angle was obliterated and a bronchogram normal.

Case 8—A housewife aged 35, was admitted with a post-pneumonic pneumococcal empyema. Twelve aspirations removed 9 pints of pus Culture became sterile in three days, and smears negative in ten days, and the patient s temperature became normal in five days She was discharged after six weeks and had returned to full household duties three weeks later

Follow up—Eighteen months later the only abnormality was 1 in. diminution in circumference of the affected chest, expansion appearing equal Radiography and bronchography were normal.

Case 9—A man, aged 27, was admitted with a pneumococcal pneumonia and a turbid effusion. Seven aspirations removed 47 oz., thick pus developing while intrapleural penicillin was continued Culture was sterile but smears showed gram positive cocci on two occasions The patient was discharged in eight weeks and returned to work seventeen weeks after admission

Follow up—Eighteen months later he had a slight smoker s cough as before this illness The affected chest was $^1/_2$ in. greater in circumference than the other Radiography and bronchography were normal.

Case 10—A man aged 27, had lost his sight and both hands in 1941 He was admitted with a pneumococcal pneumonia and sterile effusion. He was unhappy and discharged himself against advice still with an effusion. A fortnight later he was readmitted, coughing up copious foul pus and was considered to have a bronchopleural fistula The aspirated pus was also foul and contained gram positive cocci but was sterile on culture Ten aspirations removed 48 oz. of pus The fistula closed in a few days and the patient became apyrexial in three weeks. He was discharged after eight weeks

Follow up—Sixteen months later he was well There was slight impairment of percussion note at the affected base, but no other signs Radiography showed the costophrenic angle obliterated. A bronchogram was normal

Case 11—A housewife aged 26, was admitted with lobar pneumonia and a small sterile effusion. No intrapleural medication was given but after three and a half weeks a small empyema had formed The thick pus contained *Staph. aureus* and only 20 ml was obtained at two aspirations The patient improved steadily thereafter and was discharged eleven weeks after admission, having been delayed a month in waiting for a vacancy at a convalescent home

Follow up—Since then she has had a few bouts of cough and purulent sputum. Fourteen months after her discharge there was very slight diminution in expansion and a shrinkage of $^3/_4$ in on the affected side Radiography was normal, but a bronchogram showed a minute area of bronchiectasis in the posterior basic segment of the lower lobe

Case 12—A boy, aged 19, had had severe pneumonia in childhood. He had remained well, but in 1948 had had an isolated hæmoptysis In March, 1949, he was admitted with a right-sided pneumonia and a sterile but polymorphonuclear effusion. Nine aspirations withdrew 22 oz., penicillin being given each time and the fluid changing to thick pus The patient was discharged in seven and a half weeks and returned to work in twelve weeks. He remained well until April, 1950, when he was admitted with an abscess in the posterior basic segment of the right lower lobe This healed completely with medical treatment A bronchogram showed bronchiectasis of the right middle lobe and anterior basic segment of the lower lobe Re-examination of the 1948 films showed an opacity corresponding to the affected anterior basic segment. In July, 1950, the patient had only slightly diminished movement of the right side, the circumferences being equal He is awaiting lobectomy

All these patients had pus in the pleural cavity Other patients, whose fluid in the pleura, though containing polymorphs and organisms, did not constitute frank pus, have been excluded from this series though they did equally well

DISCUSSION

Aspiration, however efficiently performed, cannot remove the last trace of pus and debris Natural repair and absorption seem to be capable of clearing up the remainder This seems surprising, but lobar pneumonia is known to resolve rapidly, even though fibrin covers the lung at one stage Even with rib resection no-one can be sure that the sucker has cleared every fragment of fibrin

CONCLUSION

On the evidence of these cases there seems good reason for treating some cases of empyema with penicillin and aspiration only It is not suggested that all cases should be so treated None of the present cases was very chronic, and all had organisms sensitive, or likely to be sensitive, to penicillin There may be chronic empyemas which have reached the stage where surgery is essential. However, since twelve unselected consecutive cases made satisfactory recoveries, it suggests that this form of treatment may be more often used than hitherto, especially with the increasing number and power of new antibiotics The obvious advantages of the method are that the cavity is kept closed and that there is no wound to heal Secondary infection is less likely, and in this series a transient secondary invader was only found in four cases (*Bact coli* in two cases, *B proteus* in one case, and *Strep viridans* in one case) towards the end of treatment, and no complication ensued therefrom Frequent aspirations are no great hardship if done by an experienced man, and are probably no more discomforting than the changing of tubes and dressings which surgery requires Also there are less smell, less soiling, and less work for the nurses Perhaps very large empyemas would respond less well to this treatment In the present series the largest amount of pus removed at one aspiration was 42 oz and the largest total amount aspirated altogether was 270 oz

We are most grateful to Dr Frank Pygott for his help with the radiograms and Dr Keith Ball for his advice and criticism

CENTRAL MIDDLESEX HOSPITAL

IT is important, in judging the effectiveness of a treatment, to decide not only whether it should work but also whether it does work There are good reasons why aspiration and penicillin alone should not cure empyema, and sound theory in favour of surgical drainage All the same, if penicillin alone does work it has certain advantages Here are described twelve consecutive cases of empyema admitted under one medical firm between October, 1947, and April, 1949 All were treated with systemic and intrapleural penicillin without drainage except repeated aspirations

Brock (1947) says

> "Many of the cures of empyema by aspiration are really cures of early pleural infection It is much less likely that a mature or nearly mature empyema can be cured by aspiration alone, simply because of the adverse mechanical factors present in the thick exudate, rigid or partially rigid walls, and massive fibrin clots Penicillin is not a scavenger, it cannot clear up the battlefield the correction of the mechanical effects of infection is too much for the bodily resources To delay or to withhold surgical help to clear up the battlefield is to harm the patients, at the least, increasing the morbidity of his illness and often causing his death"

Such authoritative and logical opinion is not to be lightly disregarded, but some cases of empyema receiving penicillin as a preliminary to drainage appeared to be progressing so well that it seemed reasonable to wonder if it was true that "the correction of the mechanical effects of infection is too much for the bodily resources" It seemed justifiable to follow John Hunter's famous suggestion "Why think? Why not try the experiment?"

TECHNIQUE

Pus or infected fluid being encountered, the pleural cavity was aspirated with a 20 ml syringe and two-way tap as completely as possible and penicillin 500,000 units injected into it In addition systemic penicillin 200,000 units was given eight hourly Subsequent aspirations with intrapleural penicillin 200,000–500,000 units were usually done at intervals of 1–3 days, depending on the clinical and radiological evidence of further pus formation and the response of the patient's fever and general health Aspirations were repeated at lengthening intervals until no pus could be obtained and the patient appeared fit Breathing exercises were performed throughout treatment

FOLLOW UP

One patient could not be traced The other eleven have been followed as outpatients and at the time of writing have all reattended for questioning, chest measurements, straight radiography, and bronchography The length of follow up varies from sixteen months to thirty three months

RESULTS

There were no deaths among the twelve patients, most of whom showed a rapid improvement in fever and ymptoms from the first aspiration Fever usually ttled in fourteen days The pus became sterile on ure in about seven days (penicillinase was not used) rganisms persisted in smears for about fourteen days us disappeared (or, more accurately, none could be d by aspiration) after an average of forty days est time pus persisted to be found was seventy s, and the shortest seven days

The most striking features at follow up were the absence of symptoms and the normality in size, shape, and expansion of the affected hemithorax compared with its fellow

At the follow up ten patients had apparently recovered completely, both clinically and radiologically Case 12 undoubtedly had bronchiectasis before he developed his empyema, therefore its detection afterwards is not significant Case 11 developed a minute area of bronchiectasis She had by far the smallest empyema in the series, but a rather severe pneumonia It is difficult to believe that surgical drainage would have prevented the development of bronchiectasis in her case

The length of stay in hospital was $4^1/_2$–11 weeks, the mean being $7^1/_2$ weeks

Since none of these cases had a sinus to heal, the length of illness cannot fairly be compared with figures given by Fatti et al (1946), where recovery was judged complete when the sinus healed—i e, a mean of fifteen weeks for empyemas treated purely surgically, and seven weeks for cases treated with penicillin via intercostal drain

Some indication of the rate of recovery is shown by the interval between admission to hospital and return to normal work, which in this series was 9–17 weeks, the mean being 12 weeks

CASE RECORDS

Case 1 —A labourer, aged 57, developed a pneumonia which did not respond to sulphonamides After a fortnight he was admitted to hospital with a large empyema. Culture of the pus grew a non hæmolytic streptococcus, and eighteen aspirations removed 270 oz of fluid The aspirated pus became sterile on culture after five days, and organisms disappeared from the smear by the fourteenth day The patient became apyrexial in six days He was discharged from hospital after eight and a half weeks, and returned to work sixteen weeks after admission

Follow up —Two and three quarter-years later he was quite well There was slightly diminished movement of the affected chest, but the circumference of each side was equal. Radiography showed slight pleural thickening, and a bronchogram was normal

Case 2 —A man, aged 26, was admitted with a post-pneumonic empyema in the fourth week of his illness The pus grew a penicillin sensitive *Staph aureus* The chest was aspirated on nine occasions and 34 oz of pus removed. Culture became sterile in sixteen days and smears negative in twenty six days The patient's temperature became normal in thirteen days He was discharged in six and a half weeks, and returned to work twelve weeks after admission.
